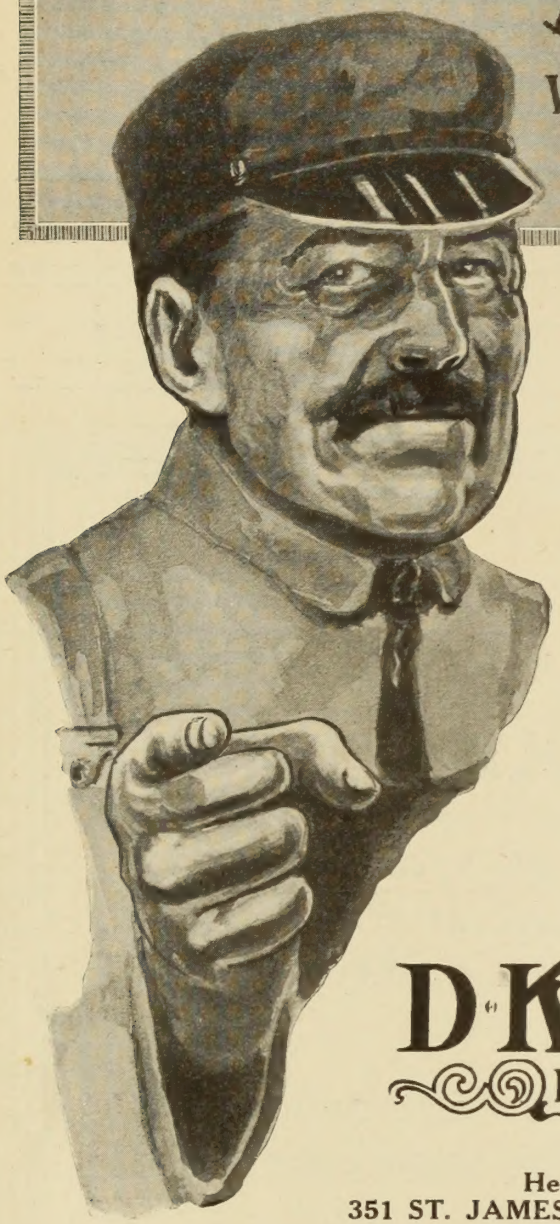
"Belting trouble ends where D.K. McLaren's Belting begins"



Do you realise—

just how much you have to leave to the efficiency of your belting—just how much you depend upon it? Imagine a break-down on your main drive—you know best what it would cost you.

Every inch of D. K. McLaren Belting can be relied upon —absolutely. Manufactured only from the **backs** of hides selected by experts; the process of genuine British Oak Tanning preserves every bit of the hide's natural strength. The painstaking final inspections and tests made are final efforts on our part to maintain the reputation for reliability so long associated with our "Genuine Oak" Trade Mark.

KAELIN ELECTRIC STEAM GENERATORS

Their Field

Any mill or factory developing its own power which has surplus electric energy during the whole or any considerable part of the day.

Any mill or factory operating on bought power purchased on a "flat rate" basis, but which is not using all the power allotted to it.

Capacities

These Electric Steam Generators are built in sizes from 600 to 25,000 K.W., corresponding approximately to 60 to 2,500 Boiler horsepower.

They can be operated by alternating current only, and are built for voltages varying from 550 to 12,000.

Advantages

Their first cost including installation is low compared with any type of coal or oil-fired boiler plant.

They are safe, clean, easily regulated, require but little attendance and take up very small floor space.

They can be operated in parallel with existing boilers or can be installed close to their work.

Information and prices promptly submitted on receipt of particulars as to your conditions.

The Tools You Buy Again

Forty years' experience and close association with users, big and small, is behind the popularity of Butterfield Tools to-day.

The standard of quality set by Butterfield Tools and maintained throughout the years is due, in part, to the policy of rigid inspections and tests before leaving our works.

These are factors of the confidence users have in Butterfield Tools — reasons why they continue to use Butterfield Tools.

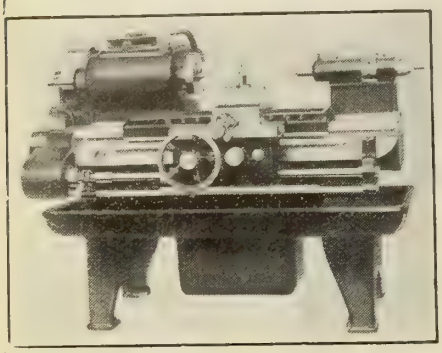
THE JOHNSON FRICTION CLUTCH

AS USED ON THE

"NEW" 12 IN. SUNDSTRAND MANUFACTURING LATHE



Progress in machine tool design demands a reliable and powerful friction clutch.

The Johnson Friction Clutch is proving of great value in machine tool designing.

Courtesy: The Rockford Tool Co., Rockford, Ill.

The main drive pulley is mounted on a No. 5 single clutch hub. The same movement that disengages the clutch automatically applies a brake whi h stops the spindle instantly. The sliding sleeve is machined to act as a brake.

A feature of the Johnson Friction Clutch is the ease of application to particular machine requirements.

The Bowser Oil Bank Will Give You a Check

To be absolutely sure that you get what you pay for in lubricating oil, check incoming shipments as barrels are emptied into the tank, then check the oil as it goes out by a meter on the Bowser piston-type measuring pump.

In this way, you are absolutely sure of getting full value for your oil dollars. Thus, the Bowser bank of oil tanks gives you a check on your oil.

More than that—the use of Bowser equipment insures you against waste. The pump measures the oil accurately, and if any happens to be spilled, it runs back into the pump through the Bowser drip pan.

For specific figures as to how you, too, can save money by installing Bowser equipment, write our engineers. Ask for booklet C-13, and get the whole Bowser story of economy and efficiency.

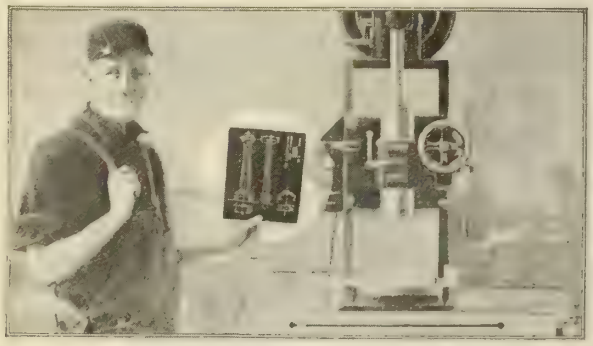
LINK-BELT



His Safeguard— a PHOTOSTAT Print

Even your most conscientious machinist doesn't have to "make sure" about any figures or lines on a PHOTOSTAT print. He knows that the print was made directly from the original drawing, not from a tracing, and

The PHOTOSTAT makes no mistake. It makes photographic facsimiles.

There is always the possibility of errors in blue prints made from tracings. PHOTOSTAT prints are absolutely accurate.

It takes hours and in some cases even days to make tracings and blue prints. PHOTOSTAT prints are produced in a few minutes.

Tracing takes a skilled draftsman. The operation of a PHOTOSTAT requires only a boy or girl.

Tracings and blue prints cost dollars. PHOTOSTAT prints cost cents.

Photostat Corporation

Executive Office: Providence, Rhode Island.

—and when the cutter was taken from the furnace he found—

That its cutting edges were hard and clean—no scale—and did not require to be ground. It meant much to have their edges clean and true to shape.

That's the kind of results you can get with Hoskins Electric Furnaces. The heat is clean and the temperature control is right under your thumb. The man who does the heat treating does not have to fuss around trying to get the right temperature—he takes care of the **tools,** and **not** the **furnace.** He gets greater production and better tools.

Hoskins Electric Furnace will save you money. Not just for tool rooms are they an economy but wherever metal is heat-treated.

Tell us the work you want done and ask for catalogue No. 122.

"P.M.S" BELTING

Built-up Plies of Cotton Duck, woven to our own specifications, and firmly united by our Rubber Friction

We have given special study to this branch of our business with the result that we supply "P.M.S" Belting in fullest confidence that it will meet successfully even the severest tests.

For Effective Service in the Transmission Field

Our research has evolved methods that secure maximum adhesion, strength of fibre and age-resisting ability. Careful vulcanization to assure correct, uniform pressure, elimination of surplus elasticity and exactly the right temperature to properly cure the belt without burning the stock is an essential scrupulously maintained.

Our belting experts will be glad to recommend a solution of your problems in belting for all transmissions, conveying of hot or cold materials, bucket elevators, or practically any kind of belt service.

An inquiry involves no obligation.

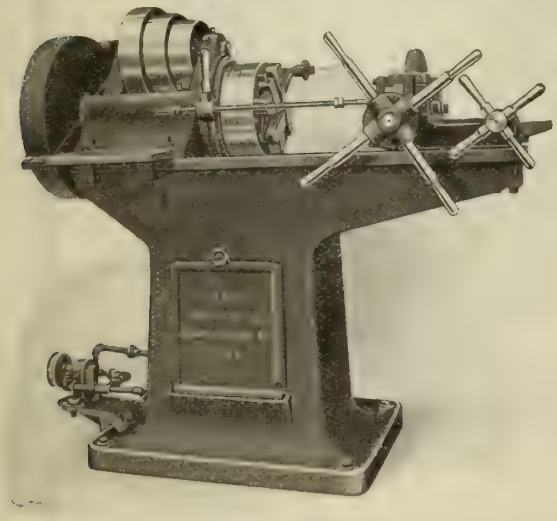
Women Operators Run the Landis Threading Machines in this Belgian Plant

The Belgian fighting spirit is still manifest; it is putting this nation back on its feet, speedily and positively (note the value of the Belgian franc). And the women are bearing their share of the burden. Here for example, are five of them running a battery of 1½ in. Landis Bolt Threading Machines, for the Liege Bolt Works.



The simplicity and convenience of Landis Machines make them ideal equipment where unskilled help is used. They can be run efficiently all day without unduly fatiguing the operators. They cut accurate clean threads, always.

Let us tell you more about the famous Landis line of Threading Machines, Die Heads, Pipe Threading and Cutting Machines, etc.

Thoroughbred Springs

RAYMOND SPRINGS—

are in every sense "Thoroughbred Springs." They owe their superiority to careful, painstaking creation by experts, whose knowledge of spring requirements comes from an intensive study of the subject for many years. In addition to this, even smallest details of their manufacture are given the same scrupulous care as obtains during the scientific heat-treatment which imparts to RAYMOND SPRINGS that attribute which places them in the "thoroughbred" class.

There is a RAYMOND SPRING for every purpose.

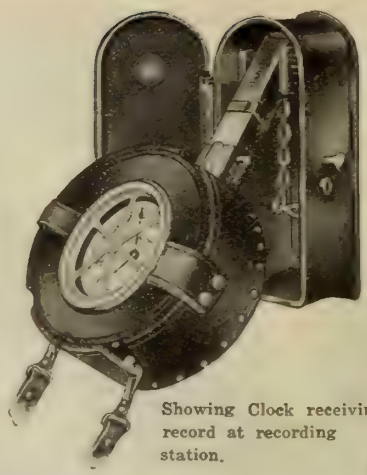
Watch Your Watchman!



Showing Clock receiving record at recording station.

WHEN you pile into your bed every night do you ever stop to realize that you are entrusting, absolutely, the source of your income to a low-salaried watchman **without proof that he is actually "on the job"?** True, you have your fire insurance, but that is merely indemnity for buildings and material destroyed. It pays you nothing for loss of production, organization and time.

The Hardinge Alert System is your Factor of Safety. It tells you, beyond argument, whether you are getting all the protection you pay for. If your watchman is "on the job," it tells you so—if he's a slacker, it tells you so. It cannot lie, the watchman makes the record himself. By his own hand he tells you whether or not he is faithful.

There's no wiring, no complicated installations to the Hardinge Alert; your workman can equip your plant in a couple of hours.

Let us send you a system for thirty days' trial.

The Beveled Edged Blades of these Squares Give Practically a Line Contact

Mechanics will be quick to appreciate this advantage of the new Starrett No. 55 Hardened Beveled Edge Squares now ready. The two edges of the blades are beveled on both sides, thus furnishing practically a line contact with the work.

Made in five sizes with length of blade varying from 1½ inches to 6 inches, and length of beam varying from 1½ inches to 4 5/16 inches.

Fully described and illustrated, with other interesting new Starrett Tools, in a special Supplement to the Starrett Catalog No. 22 3 . Copies of both this Supplement and Catalog will be promptly sent free on request. Write for them.

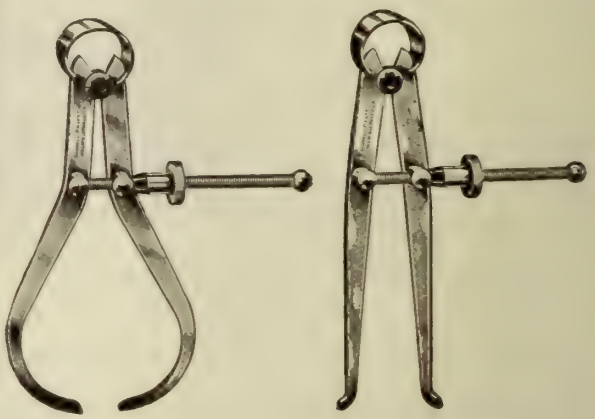
GOODELL-PRATT

1500 GOOD TOOLS

We Welcome Any Kind of Tests for Accuracy



You may be prejudiced about machinists' tools, but standards are not. If you give our precision tools the most exacting tests for accuracy in comparison with other makes, the results will be more convincing than any words of ours.

Micrometers, Rules, Squares and Gauges can all be tested for accuracy before you buy them, but Calipers can only be judged by general appearance.

Look at Goodell-Pratt Calipers, each one has well-proportioned legs of tempered steel—we don't make soft ones. The points are well shaped and come together accurately. The springs are strong and screws are smooth and even. Quick nuts work freely and do not bind.

If you are proud to own good tools write for "Tools for the Toolmaker"

Here's the Acme Upsetting and Forging Machine That Saved $398.00 on its First Run!

THESE are not our own figures, they are taken from the report of an up-to-date manufacturer in Western Pennsylvania who specializes in spokes for tractor wheels and also handles miscellaneous contract work.

In this Acme 3″ All-Steel Heading and Forging Machine, the dies are opened and closed by a powerful cam, entirely independent of the plunger slide. This gives the proper movement to "time" to the gripping slide, so necessary in forging when a large amount of stock is to be gathered or upset.

In addition to all kinds of ordinary forgings, Acme Forging Machines include within their range many intricate shapes not possible on ordinary forging machines.

DO YOU Manufacture Industrial Equipment?

Are you a manufacturer of twist drills, hack saws, mechanics' tools, wire guards, bolts, rivets, paints—do you manufacture lines of any description that can be used in machine shops, metal-working plants, power plants or foundries? If you do the publications you see illustrated here (Canadian Machinery, Canadian Foundryman, and Power House) can build a bigger demand for your products.

This group of technical newspapers is read by the men who are prospective buyers of your lines. You can bring to the attention of these men the reason why they should demand your goods when purchasing from their dealers. You can effectively do this by placing a message in the paper which serves the field in which your products are sold.

CANADIAN MACHINERY AND MANUFACTURING NEWS is published weekly and covers the machinery, iron and steel and general metal-working industries of Canada.

POWER HOUSE is published semi-monthly; it serves steam, electrical, water and gas power plants, and the power houses of all general manufacturing plants.

CANADIAN FOUNDRYMAN AND METAL INDUSTRY NEWS is published monthly; it serves the grey iron, steel and non-ferrous foundries.

Each one of these publications reach proprietors, managers, purchasing agents, foremen—the men who direct the purchasing of goods. A message to these men in any of the MacLean Technical Newspapers is certain to have a strong influence.

Write for complete Data.

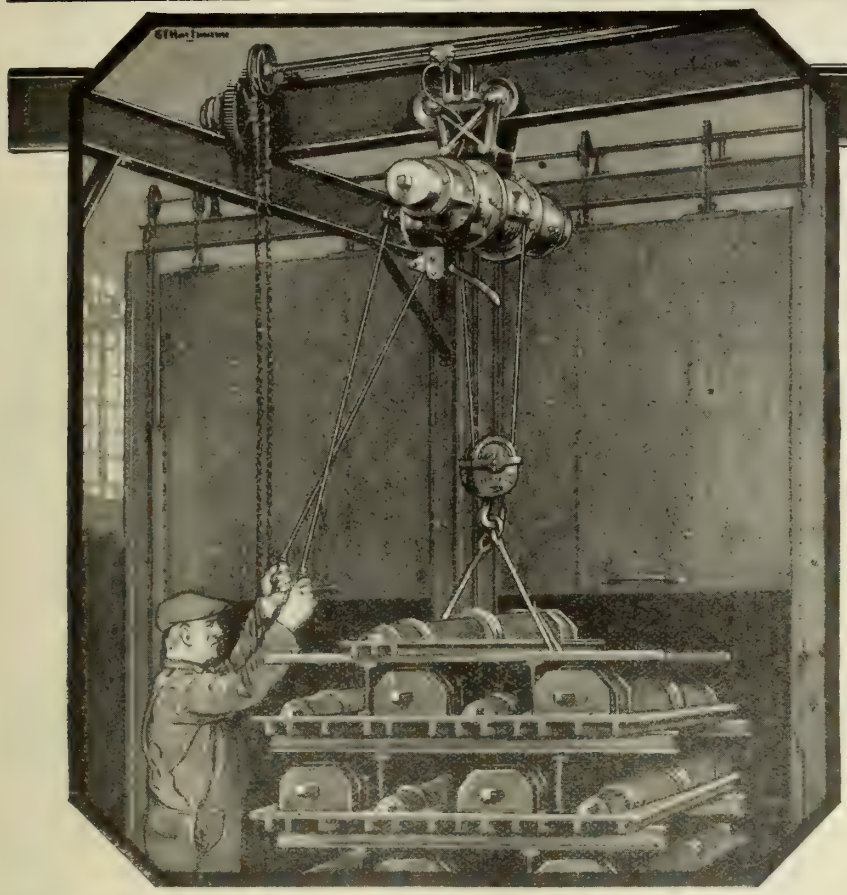
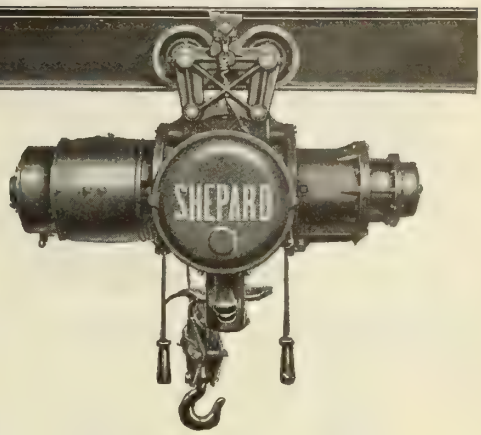
THE SHEPARD ELECTRIC LIFTABOUT





Distinctive features of construction

HOIST FRAME is shaped to rigidly support the moving parts. This casting is sealed and is flooded with oil.

MOTOR is the Zobell, fully enclosed type, designed for hoist service. For Direct Current, a standard series wound interpole motor is used. For Alternating Current, eight speeds. The controller is arranged to shut off automatically, bringing the load hook to rest when the handle is released.

SINGLE SPEED CONTROL is afforded through the use of a single switch, its only function being to start, stop, and reverse.

HOIST GEARING. Double train Shepard "Balanced Drive." Teeth are machine cut from forged steel.

MECHANICAL BRAKE. Shepard multi-disc type, operating in oil.

ELECTRIC BRAKE. Shepard multi-disc type applied directly to the motor-shaft, operating in oil.

LIMIT SWITCH. Automatic, arranged to prevent over-running of the load hook in hoisting direction.

LOAD BLOCK has cast iron sheaves and guards so cable cannot become misplaced or cause injury to workmen. The load hook is drop forged, and swivels.

HOISTING ROPE. Highest grade plow steel.

TROLLEY, OR HOIST CARRIAGE is adjustable to fit any size of beam listed. Wheels equipped with Hyatt Roller Bearings.

LUBRICATION. Continuous lubrication is provided from four reservoirs. Four openings only require oil.

ACCESSIBILITY. The motor, controller, gearing, mechanical brake, electric brake, limit switch, and winding mechanism are each absolutely independent of one another. There are no internal screws, keys, or similar parts to give trouble in taking the hoist apart. Removal of external bolts releases all internal parts, which may then be lifted out with the hands.

INTERCHANGEABILITY. Every part is interchangeable with the corresponding part of any *LiftAbout* of the same capacity.

The Shepard *LiftAbout* is making big savings in time, labor, and money in moving loads and performing all manner of rehandling operations. Economies are possible for you, and they will be a big aid in lowering production costs. Write for bulletin and complete data.

Producing Gears in Quantity at High Speed

Modern Gear Cutters Very Efficient—Multiple Fixtures Reduce Non-Productive Time—Automatic Operation Practically Eliminate Possibility of Error—Special Methods for Bevel Gears

By J. H. RODGERS

TWO GENERAL methods are used for the cutting of gear teeth; milling and planing. It is common practice to use either process for cutting teeth of spur gears, bevel gears, internal gears and racks, but the planing method is not well adapted for spiral and worm gears. On the other hand perfectly cut bevel gears can only be produced by the shaping process, owing to the gradual change in size of tooth from the outer to the inner end. Bevel gears are often cut by means of milling cutters but where great accuracy is desired the form is derived by a single edged, fixed cutter having a reciprocating motion, the tool or the work holder being given the necessary movement to retain the proper tooth shape throughout its entire length.

In the early days of gear cutting the ordinary milling machine was largely used for the purpose, where one or more gear blanks were secured on a suitable arbor supported on centres bolted to the table and moved beneath the cutter which removed the metal from between the teeth. While the fundamental principle of cutting gear teeth has not changed, the design of the modern gear cutting machine has rapidly conformed to the growing demand for heavy duty equipment capable of mass production, where speed and accuracy are the two dominating features of manufacture.

When gears are not made in large quantities it is seldom that more than one cutter is used, and this is especially true when the gears are small as regards tooth pitch. However, in the cutting of gears of large diametral or circular pitch it is advisable to use two cutters, one for roughing and one for finishing. This, of course, necessitates two cycles of operations, but owing to the possibility of greater speeds and

Illustrations and production data through courtesy of Gould and Eberhardt, Newark, N.J.

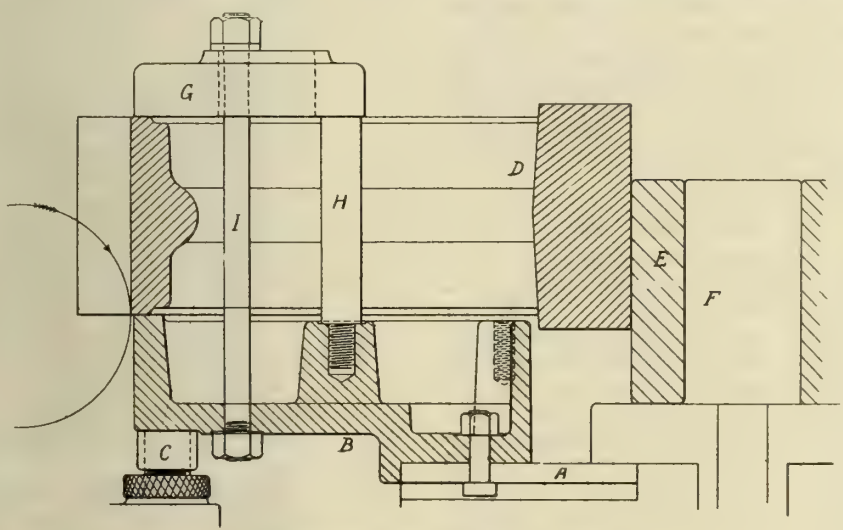

Fig. 2. Sectional View of Holding Fixture

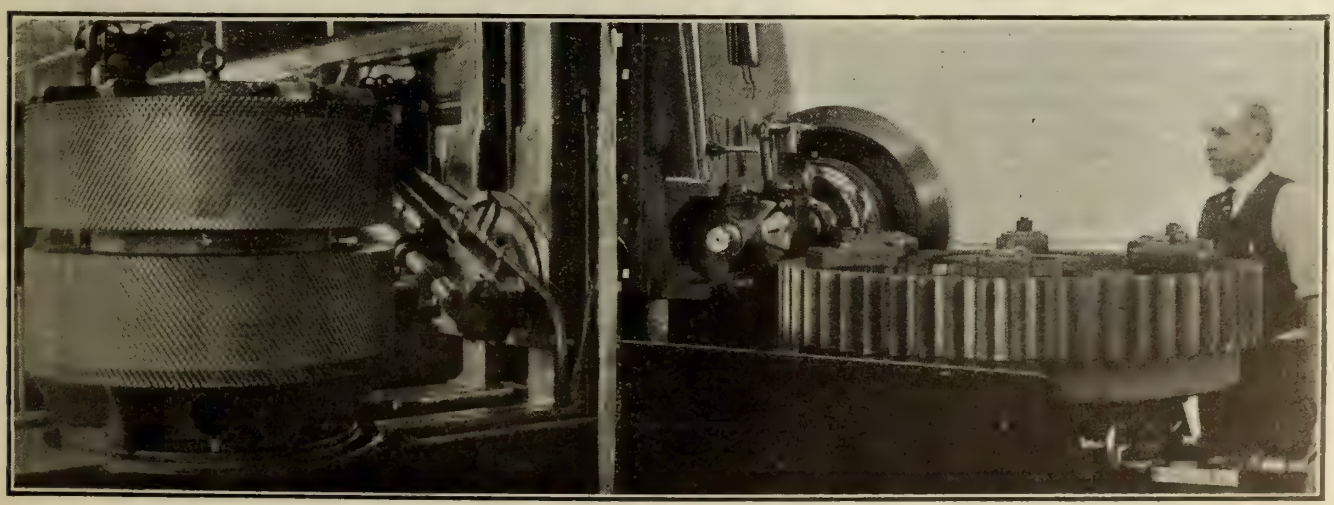

Fig. 1.—Left: cutting a large helical gear. Right: cutting large spur gear, total time 5 hours.

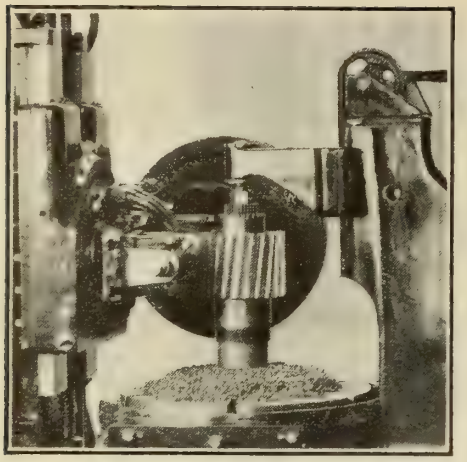

Fig. 3.—Cutting 3-pitch helical pinion, 20 teeth, 7 in. face, in twenty minutes.

feeds, and less wear on the finishing cutter the production is increased and likewise minimizes the possibility of error in the finished product.

Stepped Stocking Cutters

Where roughing or stocking cutters are used it is general practice to shape the teeth so that alternate ones cut on opposite sides, and in addition the teeth may be provided with a series of steps to break up the chips and reduce the tendency to overheat the cutter and the work. In the operation of cutters of this character it is important to see that sufficient stock is left for the finishing cut, as the action of the alternate cutting sometimes causes a weaving motion that may prevent the proper finishing of the tooth face.

Large Spur Gear

To the right of Fig. 1 is shown a 72 x 16 in. spur gear cutting machine operating on a 51-tooth, 3 in. c. p., 7½ in. face gear made of open hearth steel. This gear was finished in 5 hours from floor to floor. The roughing out was performed by a stepped stocking cutter operated at ⅛-in. feed per min. One finishing cut was taken at a feed of 2.6 in. per min.

Fig. 2 shows a line drawing of the holding device used in Fig. 1. The fixture B is fitted over the outer edge of the machine table A, which is provided with T-slots for clamping. The standard rim support C takes the thrust of the cut as the teeth are being machined. The bush E is made to suit the bore of the gear being cut and likewise the centre mandrel F. The clamp G is a steel casting slotted to take the bolt I, the stud H being screwed into the body of the fixture.

Fig. 3 shows a gear cutter at work on a helical gear such as is used in trolley cars, 20 teeth, 3 pitch and 7 in. face, made of machinery steel, finished in one cut in 20 minutes time from floor to floor.

Preparing the Blanks

While the actual cutting of the teeth is the principal factor in the gear production problem, the preparation of the blanks in large numbers is a matter of no little import. The machining is seldom performed in the engine lathe, using a single tool, but in semi-automatic or full-automatic machines, very often specially designed for the single purpose of turning out blanks of a specified size. In the automatic machines, where the blanks are made direct from bar stock or where drop forgings are fed from a magazine, multiple tooling is provided, each tool or group of tools having a specific duty to perform, operating simultaneously or in rapid succession, on different parts of the bar or blank, the actual unproductive time being reduced to the lowest degree, if not entirely eliminated On the larger gears the operations are usually divided between two machines, one taking care of the bore and hub, and the other working on the larger outside faces and diameters at reduced speeds. It is sometimes possible to mount two or three blanks on the one arbor and machine at the same time with multiple tooling arrangement.

Turret machines are particularly well adapted for the operations on the larger automotive and similar gear blanks, the work being distributed between two machines, one adapted to the chucking of the rough casting or forging and the second taking the work from the first after one side and part of the outside diameter has been faced and turned.

Bevel Gears in Quantity

In the making of bevel gears, where accuracy is essential the teeth must be produced by the generating process. This necessitates more costly equipment than the ordinary spur gear cutter, and is slower in operation—based on the amount of metal removed—but owing to the gradual change in the dimensions of the uniformed shaped tooth of bevel gears, this method of generation is necessarily imperative. How-

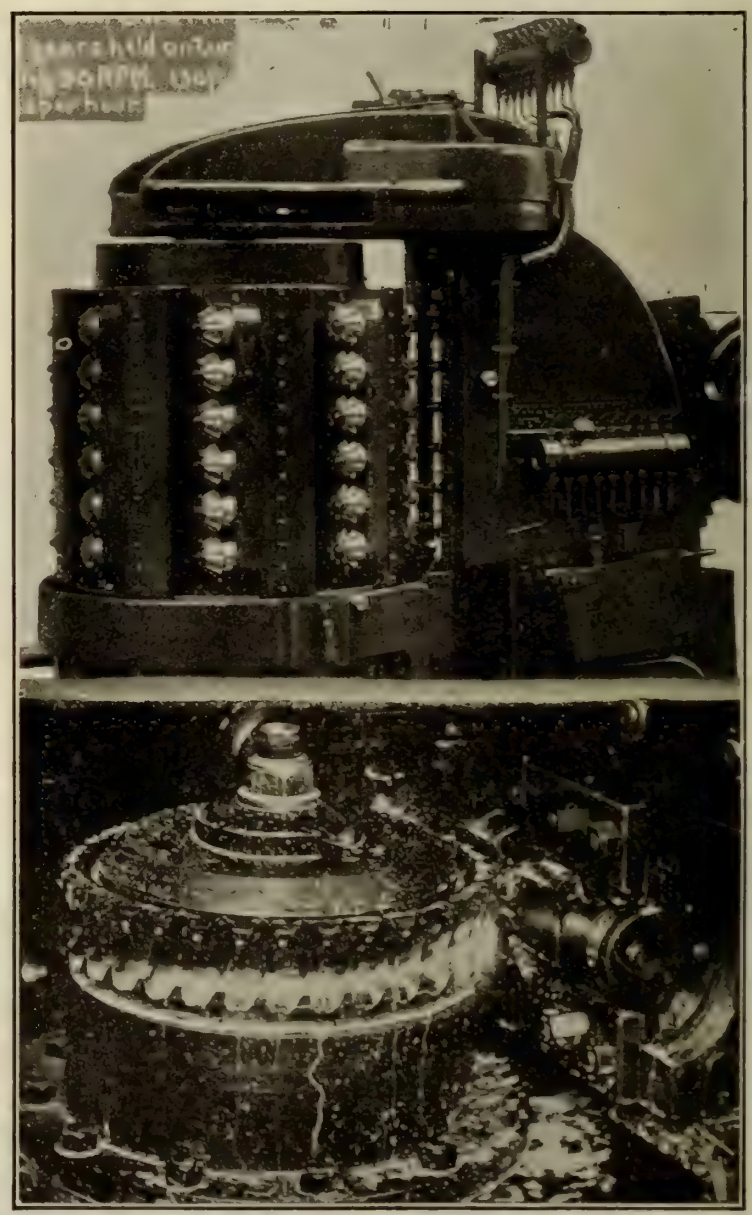

Fig. 4.—Top: special fixture for holding 48 bevel pinions, eight tiers of 6 in. each tier. Six cutters working at the same time. Bottom: hobbing a large worm wheel.

ever, this generating process is largely confined to finishing operations and the usual practice is to stock cut bevel gears by means of the ordinary spur gear method, using the forming cutter as a tool. These roughing cutters are usually made to cut as deep as the greatest depth of the tooth and no wider than the narrowest part of the tooth space.

The automobile industry has created an abnormal demand for the smaller sizes of spur and bevel gears, nearly all of which are made of alloy steel of high tensile and wearing qualities, with the maximum of strength and the minimum weight. Quality production of bevel gears has been attained largely by the adoption of mass methods of roughing out the gears before they are given the generating or finish shaping. While it is possible to group a number of spur gear blanks on the one arbor for the operation of cutting the teeth, the requirements of the bevel gear call for the mounting of each gear on its own individual arbor. For this reason quantity production resolves itself into the adoption of suitable gear holding fixtures fitted with several work arbors on which the blanks are secured, and which can be adjusted to different positions within the range of the machine. In the design of such fixtures, rigidity, compactness and convenience and speed of accurate indexing are among the important features.

Special Fixtures

An interesting and highly productive design of gear cutter fitted with a special work holding fixture is shown in top view of Fig. 4. The turret has a capacity of 48 bevel gears, six in each tier, the cutter spindle being mounted in a vertical position. This machine was constructed for the Ford Motor Co., for roughing the teeth of bevel pinions and rings which were subsequently finished by planing at another operation. The pinions in this case have 9 teeth of ¾-in. pitch. When in operation the turret revolves continuously, loading and unloading being carried on while the head is in motion. One man can look after two machines. The stocking cutters are 5 ½ in. dia. with a 2-in. hole, and run at 90 r. p. m. giving a cutting speed of about 130 ft. per min. The production is approximately 64 gears per hour

Different turrets, modified in design to suit specific requirements, can be made for other sizes of gears, the location of the arbors or turret faces being arranged to meet the needs of each individual blank. In the case of large rings the blank is held on by means of a large circular place and one clamping nut. The remounting of finished gears and the mounting of new blanks are carried on while cutting is in progress. Between cutting periods the movement of turret is speeded up seven times. At the completion of each full turn of the turret all the gears on the fixture are indexed one tooth. A machine of this type, operating on bevel gear rings mounted on an octagon turret holding 24 at one time, has roughed out vanadium steel, drip-forged gears, 40 teeth, 5 d. p., 1 in. face, at the rate of about 240 in 8 hours.

This method of multiple machining of the preliminary roughing of bevel gears is the only real economic way of aiding quantity production, as the final shaping of the teetht faces must be done individually for the reasons above stated. Even when finished with a revolving milling cutter each side of the tooth must be finished with a separate cut owing to the conical nature of bevel gear teeth.

SHOULD INDUSTRIES HEREAFTER LOCATE IN RURAL DISTRICTS?

"WHAT would you give, Mr. Manufacturer, if you could have a steady supply of labor at your busy season, out of your way in slack times, always consisting of the same contented personnel, and living happily on an income that is not entirely derived from you? Wouldn't that be a fairly satisfactory state of affairs?" asks The Industrial Digest, New York.

"But perhaps your labor problem has already been solved," the magazine continues. "Perhaps you are so much luckier than the rest of us that you can always get the right kind of hands at the right price whenever you want them. In that case you needn't bother to read this article, which is a discussion of a visionary scheme for helping to cure the labor troubles of American industry, and at the same time help solve the farm problem, the problem of city congestion and perhaps a few more of the difficulties of civilization.

"The author of the idea is Henry Ford. Mr. Ford's mind is productive of many ideas for the solution of the world's troubles. Not all of his schemes are regarded highly. But in discussing any idea of his relating to the labor problem it is worth while to remember that Mr. Ford is a highly successful manufacturer, and that his record for success with his labor is hard to beat.

"Mr. Ford's scheme is this: Let us combine factory work with farming. Let us locate our plants in country neighborhoods, and encourage our employees to own and operate farms. With the aid of modern mechanical methods they will be able to finish their agricultural duties in a short period every year, and they will have the rest of their time for factory labor.

"Is it feasible to locate industry in the country? Why not? A factory must, in most cases, be on a railroad and conveniently located in regard to its sources of raw materials and its markets; but these conditions can be, and often are, fulfilled in locations near good farm lands.

"When large corporations create towns in which their workers can live they usually encourage the men to cultivate little garden plots behind their houses. There is a great difference, of course, between a garden plot and a farm, yet to urge workers to grow their own cabbages is a step, however small, in the direction of Mr. Ford's ideal condition.

"If that condition could be made to prevail, it would be wonderfully beneficial for all hands. It would mean satisfied, cheap labor for the manufacturer and a fuller, happier existence for the combined farmer and factory worker. It is a vision for the future, and most of us have all we can do to take care of the present; yet if we are to make the most of the present we must keep the future, too, in mind. Mr. Ford's idea may not be practical. It is at least worth thinking about."

HEAT TREATMENT OF CAST IRON

Grey iron castings very seldom receive heat treatment of any kind, being used just as they leave the moulds. The benefits resulting from proper heat treatment are many. Take, for example, a lathe bed casting. Some engineering firms rough machine such castings, then leave them out in the weather for several months for "seasoning." The reason given for this is that "if a lathe bed casting is machined and finished without seasoning, it twists and goes out of shape, and the lathe is no longer accurate." Why? In a lathe bed or similar casting, where unequal thicknesses of metal are joined together, internal stresses are set up by the contraction at different times of the various thicknesses of metal, assisted to an extent by the cores. When the skin of the casting is broken these stresses begin to assert themselves, and in time pull the casting out of shape, and no period of sun and weather will ever completely take these stresses out. Heat treatment will.

Castings of unequal thickness of metal, where accuracy in the finished machine is desired, states a writer in Hardware and Machinery, ought to be heated slowly to 550 deg. Cent., held at that temperature for at least twelve hours, and then allowed to cool slowly in the furnace. This will give a casting which will not only keep its shape, but possess the maximum strength in all parts. Hard spots in medium castings and all hard light castings are very often the result of chill from water. When these faults are found the results from the machine shop are far from satisfactory, broken drills and reject castings being numerous. To stop this the castings ought to be heated to 850 deg. Cent., held at that temperature for two hours, and then allowed to cool slowly in the furnace. For both of these heating operations muffles or steel boxes, securely luted with fire clay to prevent oxidation, should be used. Not only so, but the castings should be painted over with powdered charcoal or coke and water.

Half Year's Business Retrospect and Prospect

Seasonal Work Helping Unemployment—Wage Standards Fairly Well Maintained for Skilled Work—Warning Against "Building Orgy"—Motor Industry Promising—Better Outlook for Railways—Freight Reductions Effective Aug. 1

AS a matter of history, the first six months of 1922 are not without good features, nor does the future lack cause for optimism. Unemployment in the early weeks of the year was serious. At one time the number of personal enquiries handled by the employment service of Canada in Toronto alone was something like 20,000 weekly. Many of these, of course, were repeats—that is, men who, having filled temporary jobs, necessarily made second or third applications, while in more serious periods, it was required of men seeking relief, to call daily. So that the figure is hardly so serious as it may seem. Seasonal work has brought about a marked improvement. Construction, railway and farm work has absorbed thousands of men. The opening of navigation makes its demand, and large engineering works have assisted in the easing process.

Farmers are keen to get good men and for the summer the wage rates are $35 to $40 monthly, everything found, for experienced men. Some effort is being made to have farmers hire their men by the year on a basis that will allow for the higher wage during the heavy months and for a wage considerably lower in the winter, or the so-called slack period.

Low Rates For Railway Labor

Except as regards railroad laborers, wages seem to be held at a reasonable standard, living cost levels being considered. Men for railroad contracts have been cleared through the employment service at 25 and 30 cents an hour, a ridiculous wage, and one that has called forth some protest from the service, but, contractors reply, "if you can't get us the men at that figure, we will get them elsewhere." The supply has been quite up to the demand.

On city work in Toronto, no laborer is paid less than 60 cents an hour, the Toronto Transportation Commission is paying 40 to 55 cents, while it is stated that men for lumber camp work are being contracted for at 26 to 32 cents an hour, everything found. It goes without saying that the cost of taking out lumber is going to be on a much lower scale than formerly.

Warning Against "Building Orgie"

Building trade activity has been one of the bright spots. For the most part, the trades engaged here are fairly well organized, and the wage represents a better standard of living. Wages to skilled men range from 75 cents to $1.00 an hour, with the higher figures generally ruling in the Western provinces.

Building materials have held firm. There has been strong demand for all materials, particularly in the larger centres of population. Opinion seems to differ as to whether the building activity was merely a spasmodic spurt or the forerunner of sound recovery. There are said to be 6,000 houses in course of erection in Toronto this summer. Referring to this fact, a prominent bank official expressed the opinion to Canadian Machinery, that such a number of houses would seem adequate for the immediate requirements of that city. He expressed a fear that if what he called "a building orgy" set in, and the supply outstripped the demand, stagnation in the building trades might result greatly to the detriment of healthy, stable growth. He further predicted that a decline was about due in real estate prices. This was a department, he stated, in which no deflation had occurred and he considered that such development was due.

Little Demand For Credits

"So far as industry as represented by your medium, is concerned," said this official, "about all that can be said is that the banks are meeting the requirements of industry. Generally speaking, people have not been asking for credits during the past six months, except in very few lines representing individual effort, where a good selling specialty may be concerned. People doing business with a standard line, say in the machinery field, have probably felt the falling off in demand more seriously than in the specialties. There has been an easing off in the security markets, bonds have had a slight recession, the best industrial stocks are holding up in a way that suggests an undertone of confidence, and I would say that, at heart, things are sound. The only warning that seems necessary is against overdoing anything that looks like an honest-to-goodness return to prosperity, and against the risking of money in schemes or undertakings which investigation will prove to be practically worthless. Such times as those through which we are passing seem to nourish that kind of speculation. It seems to be good advice, that people should consider their hard earned money as something that should still be handled carefully. They may need it."

Manufacturers of machine tools do not report much improvement in the situation, except in the woodworking section. Here, the activity in furniture and lumber industries has helped to keep industry on its feet. The demand here is regarded as largely an outcropping of the improvement in building operations. In the employment service, the information is given out that in the meantime, machinists and other skilled men in that class, have been taking employment in other lines.

Buying By Railroads

The appearance of the railroads in the market for material is regarded as an encouraging sign. In the United States, the railroads have been heavy buyers for the past three months, and the demand from this quarter has been a great factor in maintaining a most active market. The coal strike has also contributed to a firming tendency in steel and iron prices. While reports indicate the Canadian lines to be in good condition, so far as rolling stock is concerned, road requirements seem to be receiving attention. The Algoma Steel Corporation, for example, has received an order from the C. P. R. for 48,000 tons of rails. The rail mill there had not been operating for the past six weeks. Reports from Sault Ste Marie state that "as general steel business is now improving, it is expected that enough business will be secured to keep the plant running steadily. Beginning Sunday night, it is expected that the whole plant will go on double shift with a full force." The Nova Scotia Steel Co. also reports activity as the result of railway buying.

The foundry industry seems to have survived a bad three months at the beginning of the year, although it is still evident that most business is being done where there is contract with thriving conditions in the building trades. Builders' hardware, plumbing and drainage supplies have been in great demand and this has helped foundry business. On the other hand, up to one month ago, there had been little doing in the agricultural implement industry. Foundries that have always depended on this source of business, have been disappointed and have been going after general work to tide them over. However, there is a change for the better here, owing to good crop outlook, and the prospect of a better Autumn business in implements. The motor car industry has also been a helping factor here.

Increased Production in Motor Cars

Whether or not it may be considered a seasonal industry, the manufacture of motor cars in Canada would seem to be measuring up to the prediction that the year 1922 would be just what it should have been had there been no war and no post-war inflation, and that in 1923 the normal increase in demand should fully require the enlarged production capacity planned in more propitious times.

In fact, the motor car industry will figure largely in the extensive building operations of the near future, and some

plants have already been announced. The large, potential export market for cars, represented by the British Empire, is in large measure responsible for the growth of the industry in Canada. Preferential tariffs have been an advantageous factor.

Freight Rate Reduction

The most that can be said about railway business during the past six months is that reports reflect general conditions. The month of May was in some respects exceptional. One road reports an increase in carload lots in the east. Crop prospects are good, and the feeling in railroad circles is that reports from now on should show improvement. Some impetus is looked for as the result of the reductions in freight rates ordered for August by the Dominion Board of Railway Commissioners. The reduction is on basic commodities—forest products, including pulpwood west of Port Arthur, building material, brick, cement, lime and plaster, potatoes, fertilizers (other than chemicals) ores, pig iron, booms, billets, wire rod, and scrap iron—and amounts to 7½ per cent. from existing freight rates. The decrease reduces the increase of September, 1920 to 12½ per cent. in Western Canada and 17½ per cent. in Eastern Canada. Grain and flour rates were fixed in accordance with the rates prevailing under the Crows Nest Pass agreement, and the order rescinds all increases provided for in September, 1920, on coal, other than anthracite and coal from the head of the lakes westward. Important decisions affecting the railroads have also been made in the United States. A horizontal cut of 10 per cent. has been made in freight rates, a reduction to 5¾ per cent. of the "fair return" basis for purposes of fixing rates, and a series of wage reductions affecting 800,000 men.

Delicate adjustment is required in the fixing of freight rates, the problem in Canada being accentuated by varying conditions as between East and West in the matter of business possibility and upkeep. Time seems to be the only satisfactory test of freight rate changes, for in fixing relief to the shipper there has also to be consideration of earnings of the railroads in order that investment may have reasonable protection. The announced reductions mean a loss in revenue of about eleven millions each to C. P. R. and Canadian National. The new rates are in any event, a step toward normal, and hence not unwelcome to shippers, however divergent outside views may be.

On the whole, it may be said of industry, that the advent of the year's second half, is marked, at least, by greater degree of stability than has been evident for some time. Caution is advisable, but at the same time, the view seems somewhat clarified and not without its encouragement for well-directed effort. Summer months will see an easing off in manufacturing and in general demand, but there seems in many quarters a feeling that some confidence may be reposed in the prediction that from the mid-year onward the general industrial trend would be upward.

ENGINEERING FIRM IN GROUP LIFE PLAN

FROM time to time Canadian Machinery is asked for information with reference to the operation of group life insurance. One of the most recent contracts entered into in a large way is that of Dwight P. Robinson & Co., engineers and constructors, New York, with branch office in Montreal. By arrangement with an insurance company, life policies are provided without expense to individuals for all employees reporting to the central group office under a group insurance plan. This insurance is without cost to the employees and its benefits are in addition to those provided by law under compensation acts.

All employees included in the plan are insured regardless of their age and condition of health and no medical or physical examination is required. The amount of insurance is increased $100 for each additional year of continuous employment and this plan of regular increase is thus a recognition of length of service. Each employee has the privilege of naming his or her beneficiary which may be changed if necessary, and individual policies are issued to each insured employee as evidence of the coverage. Not only life insurance but provision for total and permanent disability before the age of sixty is included in the contract. In case of disability the amount of insurance stated on the certificate is paid to the insured in monthly or annual instalments. If death occur during this period of disability, the remaining amount is paid to the beneficiary.

The Insurance Company maintains a plan, which includes the furnishing of professional graduate nurses to the homes of employees covered under group policies in case of illness. The nurse's duties are to assist in carrying out the instructions of the physician in charge, advising members of the household in the proper care of patients and visiting the homes as often as may be needed. It also maintains a complete course of literature and lectures dealing with matters of health, hygiene and disease prevention.

CANADA'S PETROLEUM FIELDS MAY BECOME WORLD'S GREATEST

"SIXTY per cent. of the world's total supply of oil is now produced in this country, but U. S. fields are becoming exhausted, and geologists expect their early decline. When our petroleum is used up where will the bulk of the world's oil come from?" asks The Industrial Digest, New York. "A large part will undoubtedly come from Canada, whose oil fields have enormous potentialities. In western Canada are petroleum territories which have scarcely been tapped, but which, when they are developed, may make our northern neighbor one of the foremost oil-producing countries of the world. "According to latest government statistics, Canada's annual oil production up to date stops short of 310,000 barrels (90 per cent. from the Ontario fields) in comparison with more than 330,000,000 barrels produced by the United States.

"If we take a map of Canada and very roughly draw a line from east of the Great Slave Lake, passing through Lake Athabasca down to the north end of Lake Winnipeg, along the east shore of that lake to its southerly end, thence to and along the north shore of Lake Superior to the Soo, and thence along the northerly shore of the Georgian Bay to Parry Sound, thence due east to the St. Lawrence River, and along the northerly bank of that river to its mouth, we shall have divided the Dominion into two vast areas, that lying to the northward of our line being regarded as generally hopeless for oil prospecting, that lying westward and southward being from its geological formation rich in promise for the finding of productive oil fields within the economical range of practical drilling.

"If we further examine the geological map of this latter area, we find that the great oil-bearing strata of the North American continent, which in the United States have been productive of the richest and most prolific oil reservoirs of the world, contributing in fact in excess of 60 per cent. of the world's total oil supply, constitute the principal geological formations and out-crops of this vast Canadian territory. All of these geological formations contribute in the various oil fields of the United States to the vast total production of the country.

"It requires, therefore, no more than an average share of optimism to predict that Canada's future as a world oil producer is certain, and only awaits the assured results of time and capital expended on the scientific location of favorable structures of these formations and their subsequent exploration by the drill."

REMOVING RUST FROM TOOLS

Tools that have become very rusty should be treated with a chemical solution, instead of trying to scour the rust off by means of emery cloth. A good solution for removing rust may be mad as follows: Into one quart of distilled water dissolve, little by little, sufficient chloride of tin to obtain a saturated solution, that is, until the water will not dissolve any more of the salts. Put the tool into a receptacle containing the solution and let it stand over night. In the morning rinse the solution off in running water and dry thoroughly with a piece of chamois or cloth.

Hints on Setting Up and Clamping Work on Planer

Planing Machines Require Good Foundation—Keep Wearing Surfaces Free From Chips and Dirt—Protecting Tool on Return Stroke—Multiple Tooling and Production

By H. ALTON

THE problem of getting the most work in a given time from a planing machine is one largely up to the shop foreman or superintendent. As the planer does not lend itself to varied settings and multiple tool setups to the same extent as some designs of lathes, many foremen pay little attention to planer work, allowing the operator of planer to take care of the work largely as his fancy dictates. Such a policy does not produce the best results, and there are but few shops operating planers to-day that cannot increase not only the efficiency of such machines but range of usefulness.

Setting and Aligning Planer

The bed of a planer should always be placed on a concrete foundation in order that perfect alignment of the Vees may be maintained. Work can never be accurate unless the Vees are in perfect alignment.

A common mistake, that is often made in setting a planer, is to place the machine on a level concrete foundation, wedge it up until the platen is level, then group it in. It is common knowledge that planer Vees tend to wear low in the middle, and for that reason it is always advisable to set the centre of the Vees of a new machine one or two thousandths of an inch higher than the ends. Thus until the Vees wear one or two thousandths low in the centre, work can be very accurately planed. If this point is not taken into consideration a machine will much sooner tend to produce "hollow" work.

A very good type of planer bed wedge is shown at "A" Fig. 1. These wedges are set into pockets in the concrete foundation and are spaced as shown at B and C for large and small planers of the legless type. When the adjustable wedges are set, it is not a difficult job to level a planer bed. It is necessary to have two accurately sized cylinder plugs like those shown at A in Fig. 2, a test bar similar to that shown at B, and a precision level. In the case of planers having end legs it is only necessary to level crosswise, at one end, while the other end is levelled both ways. With the legless variety, levels are tested both ways, as shown in Fig. 2 and 3 proceeding as indicated by the dotted lines in Fig. 4, working to both ends from the centre.

In some small shops a precision level is not available, but such a contingency need not keep the small shop man from leveling his planer bed. A gallon or two of kerosene and a few odd lengths of pipe will give extremely accurate results. The Vees are dammed at each end as shown in Fig. 5, and connected together with a pipe at one end to maintain the level. A surface gauge on a block which fits the Vees is moved along, and carried from one side to the other while the wedges are adjusted until the liquid surface is at the same distance from the gauge point at all places.

Capillary attraction makes the liquid surface rise to meet the needle, as seen under the magnifying glass. This occurs when the point is about two one-thousandths of an inch above the surface, and this fact can be used as a guide when levelling.

It is often the case that even new planers will refuse to plane square on the down feed when the saddle swivel scale is set at zero. When a competent planer-hand tackles a new machine, his first idea, after oiling up, is to find its errors, and he goes after a new zero line for the saddle-scale, as shown in Fig. 6, using an accurate square and a test indicator held in the tool block.

When one considers the backlash of the elevating screw gears, lost motion in the elevating nuts, wear on the threads of the screws, the short bearing that the cross rail has on the housings, and the weight of the cross rail itself, it is surprising how any planer can plane square with the table, after the cross rail has once been moved. The alignment of rail is maintained principally by the elevating screws, and to get best results it is always common practice after lowering the head to raise it a little again, to take out all backlash. It is very necessary to keep the elevating screws free from dirt and grit, and well oiled, if ordinary accuracy is to be maintained. When exceptionally close work is required it is best to test each setting of the cross rail as shown in Fig. 7.

A planer is a bulky and heavy machine, this fact ensuring long life. When figuring depreciation it is usually estimated over a much longer period than other machines such as lathes. On large planers it is common practice to assume they will be used for a period of twenty-five years or more.

The Accurate Planer Considered as a Precision Machine

To gauge and measure a flat surface is more difficult than to gauge a round one. For that reason many planers are finishing work to-day that is not as accurate as it is assumed to be. Therefore, one of the possible explanations for the longer life of a planing machine lies in the fact that it is very difficult to test accurately the flatness of a surface, and inaccurate and worn machines are thus permitted to operate.

In spite of this, when carefully looked after and properly operated, a planer not only can, but does, form the basis for the accuracy of all other machine tools. Upon it is produced the final shape of nearly all flat sliding surfaces, which, while they may be further smoothed and rectified by hand scraping or grinding, must owe their initial and a great part of their final measure of accuracy to the planer.

Some machines are subject to more or less hard usage and abuse owing to the fact that they are supposed to have a long life. Some mechanics regard a planer as a heavy chunk of metal capable of withstanding almost anything, while in reality an accurate planer is a delicate

machine. It is a rare thing to find planer Vees that have been used for any length of time, that are not scratched, or more or less corrugated with deep gauges and crevices. The Vees, which are the vital parts of the planer, often get less consideration than the top of the platen.

Many planers get old fashioned and out of date long before they wear out. Planers designed and sold a few years before the advent of high speed steel are, so to speak, still in their prime. They are geared to run between 15 and 20 feet per minute on the cutting stroke and between 40 and 50 feet per minute on the return. Most of these machines in service to-day are completing work at a somewhat faster rate and it remains to be seen if the length of their days will be shortened. Many difficulties are met with in re-speeding old planers. The inertia of the moving parts is great, and at higher speeds the belts give an endless amount of trouble.

A common idea is that the great amount of power required to reverse a planer is due to the weight of its heavy table. It has been shown however, that the thing which makes a planer hard to reverse is the inertia of the fast revolving driving and overhead pulleys, which have to be brought to a dead stop and reversed within a short period of time. Some mathematical genius has figured out that it takes from eight to twelve times as much energy to bring these rotating parts to a stop and reverse them, as it does to reverse the planer tabe. This same mathematician figured out that in the course of a day of ten hours a pair of planer belts slip, on an average, five miles. Planer belts always should be endless, as the constant shifting from tight to loose pulleys is destructive to all forms of laced joints. Double belting is best, because it will not stretch as quickly as single belting, therefore requires less cutting and shortening.

Planers are all subject to belt troubles and as this is a necessary problem it must be accepted. Therefore, it is essential to inspect the belts periodically, cutting them and making the necessary

glued joints. The older designs did not experience the same belt troubles as they moved more slowly, in some cases it has been found that belt troubles on re-speeded planer caused so much idle time that less work was actually accomplished. The best solution of the old planer problem is not to speed it up too much, but to increase the feed, in this way bringing its capacity for removing metal, up in the neighborhood of the modern machine. The latest style of planers are geared to take care of most of these troubles. They are designed to rough cut cast iron at from 40 to 50 feet per minute, and to handle steel castings and machinery steel at from 30 to 35 feet per minute. Return speeds as high as 100 feet per minute are not considered excessive.

Use and Abuse of a Planer

Before considering the intensive idea of planing by the use of several heads, electric drive, and other distinctly modern applications, we will look into some of the things that can be done with the single head on the cross slide. A planer must be kept well oiled at all times, and the Vees must be kept not only well oiled but scrupulously clean and free from all dirt, grit and foreign matter. Chips should be kept out of the gears.

When planing short jobs it is always good practice to place the work near the end of the table. This distributes the wear on the Vees and does not tend to wear them low in the centre, as much as if the work were placed on the centre of the table. When planing long work, and the tool is directly over the Vees, there is every probability that some chips from the overflowing pockets at the end of table will fall in the Vees. This should be anticipated and provision made to prevent its occurrence by never allowing the pockets to get full to the point of overflowing. In fact each reversal is quite apt to dislodge a few chips. When rough sandy castings are being machined, means should be taken to protect the surface of platen. Castings should never be moved with a crow-bar inserted in the holes of platen, and if it is necessary to slide castings, put old strips of belt leather or pieces of thin wood under them. All holes and slots in platen should be plugged with wood, and these plugs can be easily removed from any holes or slots it is necessary to use. Should any burrs be raised on the table they should be immediately removed.

In all forms of clamps get the bolt as close to the work as possible, and as far from the clamp block as conditions will permit. Hard maple with the grain on ends makes the best blocks. It is not good practice to pull the nuts down too tight.

In planing unannealed castings, or castings that have not been seasoned, particularly on work where large areas of scale are removed, it is always a good precaution to release the clamps before the finishing cut is taken to allow possible internal strains to become equalized. Then, only lightly clamp the work for the finishing cut. Work should always be well supported by

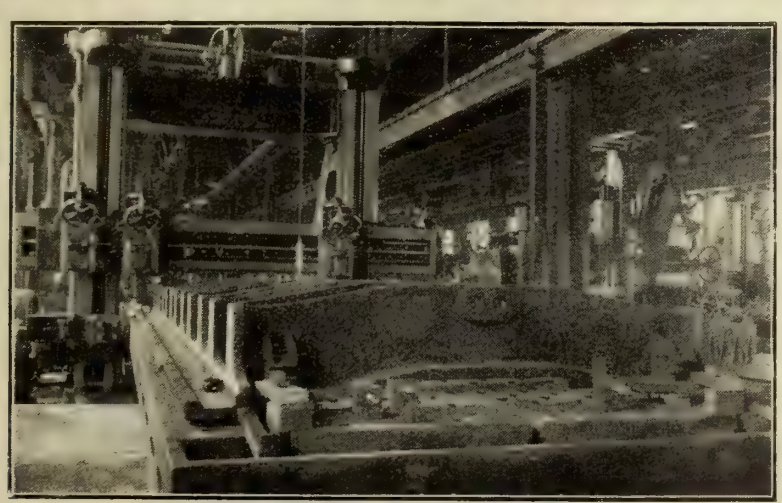

Fig. 16—Large modern electric driven planer with five heads.

blocks so that the tool pressure will not distort. All overhanging pieces that have to be finished should also be well supported.

The practice of pulling nuts down very tightly is the source of a good many troubles. Castings are often strained and sometimes broken from this cause. Clamping nuts and bolts often have their threads ruined. With a properly ground tool there is not much tendency for work to "lift" when it is being planed. Provide good substantial stops and get the work located positively against the stops, and then only a nominal amount of clamping will be sufficient.

One point that only a few planer hands seem to appreciate is that it is extremely bad practice to allow a planer to take its feed at the end of the cutting stroke. It is even more disastrous if rough castings are being machined. When this practice is resorted to, the cutting edge drags on the work all the way on the back stroke, and if sand and scale are encountered, the fine cutting edge of the tool is ground off after the first few strokes.

A goose-neck tool such as shown in Fig. 8 at "A" will scrape a casting fairly smooth. A finishing tool such as shown at "B" in Fig. 8, ground with not over 5 degrees clearance on the bottom, gripped close to the tool block, and with the rail as near the work as it can be placed, will never dig in, and will give as smooth a surface as the goose-neck tool, and in addition, one that is as true as the planer Vees. An old superintendent the writer had the pleasure of working under used to say, "You can pretty nearly figure planer accuracy and planer profits by measuring the distance between the top of the work and the bottom of the cross rail, the greater the distance the less accuracy and profits." Experience goes to show he was pretty nearly correct in his reasoning. Fig. 9 shows a kink that is overlooked in many shops. When work is being held in a planer, shaper, or miller chuck, the solid, or dead jaw must always be reckoned with for the alignment of the piece that has to be planed. By placing a round bar between the live jaw and the work, the latter is forced against the true surface of the dead jaw and materially assists in producing square work.

Time is lost on many planer jobs by putting on too many clamps, and using too little judgment. As stated previously a properly ground planer tool will tend to lift the work, but will rather tend to thrust downward and against the motion of the platen. Work properly stopped endwise does not need much clamping and can be held sideways by means of stops as shown in Fig. 10, any one of which may be applied in much less time than the ordinary U-clamps. The square side bars, in connection with the smaller screw stops "B" and "C" in reality take the place of a planer chuck and usually pay for themselves in a short time.

There is plenty of room for discussion of finishing cuts on planers, especially in cases where extreme accuracy is not required. The tool shown in Fig. 11 is one capable of taking a six inch cut, and of being fed at a rate of four inches per stroke. The cast iron block which holds the cutting tool is bolted solidly to the clapper block and is very rigidly supported. A tool of this kind if given a shearing cut will do excellent work without any tendency to dig in, but it must be carefully set in its holder, to have the cutting edge dead level with the platen. This is accomplished by using two accurate squares, and adjusting the tool till no daylight is seen between the edge of the square and the cutting edge of the tool.

Fig. 12 shows the use of pin clamps where thin work is being planed, while Fig. 13 illustrates how sheets can be split on a planer.

Jobbing Work on Planer

In shops where repair, jobbing and contract work is the rule, rather than manufacturing, a number of angle plates for the planer are good revenue producers. Where a keyseating apparatus does not exist the planer can be used for keyseating purposes. Fig. 14 diagrammatically represents how this is accomplished. Bar tool "A" is clamped in the clapper block. A wooden block with a stiff coil spring is placed as shown at "B." The bar "C" is fastened in the bar "A" and the two set screws are tightened against the bar "C" which has a small flat on its side to receive these screws. The keyseating tool "D" is tightened in bar "C." This tool is squared up with planer platen by means of two squares. The bar "C" should only extend from the bar "A" far enough to permit the tool to pass completely through the bore without interference. An angle plate is then placed on planer against two square headed stops as shown at E. Next the strip "F" is placed under the angle plate as shown. This gives taper to the keyway to be cut, and the thickness of the strip should be calculated to give the standard taper. If in keyseating pulleys with extended hubs, bevel gears, or pieces that have been faced on one side only, it is found more advantageous to clamp them on one side than on the other, it may be found the key will drive from the wrong side if the strip "F" is placed where shown. In order to correct this, the strip is placed next to the stops at "E." Then the pulley or part to be keyseated is clamped to the angle plate. A hole is located in the angle plate at "G." Straight edge strips are used to hold the work away from the angle plate and to allow the operator to see the tool as it comes through the hub. In cases where large pieces are to be keyseated, long straight-edges, extending above angle plate can be used. If the keyseat is too wide for a single tool, a narrow tool can be used to hog out the metal, and the full sized tool run through to finish and and size the keyseat. Care must be taken in centering the tool when starting. Work of this nature can be quickly and accurately completed.

The cutting of keyseats in shafts is a rather simple matter on the planer. Perhaps the average mechanic does not realize that a large number of spur gears are being cut on planers every week. Special dividing heads are used for this purpose. The indexing is through the medium of a worm and worm gear and a set of change gears, mounted in a suitable frame so as to operate an arbor. The arbor is fitted with a number of removable pins which are tapered and fit into the main arbor, for different bores as shown in Fig. 15. The method of clamping gear is shown. For special bores, collars are placed on the pins as indicated in Fig. 15, and if a blank is to be cut, a roughing tool gouges out the metal, then a finishing tool the proper shape of the tooth space is run down.

(To be Continued)

Important Points in Joining Ends of Belting

Leather Lacing Still a Favorite—Lace Holes Reduce Ultimate Strength of Belt—Joint Should Run Smoothly Over the Pulley—Making An Endless Joint

By LOUIS W. ARNY

PROBABLY the greatest source of annoyance in the use of any kind of power transmission belt is that arising from the difficulty of properly joining the two ends. This is often done with lace leather, and a laced joint is a good one, if well made, and it still is a favorite. There is too, a wide variety of metal fastenings for this purpose, and some of them are not so bad as some others. In the various fabric belts resort must be had to lace leather or to the metal devices, for though it is possible that rubber belts, and some other varieties of fabric belts, may be made endless in the process of manufacture, they are very troublesome to install on their pulleys, necessitating often the taking down of shafting, etc., and they will run but a short time when they have stretched enough to make it necessary to cut the belt to shorten it, and then resource to lace leather or metal fastenings becomes necessary. Where these belts run with a tightener, which will take up all the stretch of service, this endless joint will make no trouble, but where there is no provision for taking up the stretch, or where the swing of the tightener is not large enough to provide for all the stretch, there is frequent trouble with the lace holes cutting out, or the metal fastenings breaking, or the ends of the belts tearing. The joining of the two ends, therefore, is the weakest and most troublesome point in any belt.

Method of Fastening

The requirements of a good method of fastening the ends of belts are, first, that it shall be strong. The tensile strength of leather belts is from 3,500 to 5,000 lbs. per. sq. in., and of the fabric belts even higher, and the strength of the fastening should be approximately as much, even though the strains of operation are much less, for the belt is no stronger than its weakest point. It is true that no belt ever operates under any such load. Mr. Jones, research director of The Leather Belting Exchange Foundation, at Cornell University, reports that the greatest load he has ever been able to place on a belt and keep it upon the pulleys, is about 1,000 lbs. per eq. in. on a lether belt, and the difference between the figure and ultimate tensile strength of the belt seems an ample margin of safety, indeed much greater than it is customary to provide in other materials, but the high tensile strength requirements of leather and other kinds of belting are considered necessary to insure the presence of other qualities which are requisite to a good belt. It seems foolish, however, to spend good money for a belt to stand a tensile strain of 2,500 to 3,500 lbs. and then to fasten the ends with devices that will break or pull out at 1,500 to 2,000 lbs.

Author is secretary of the Leather Belting Exchange.

Strength of Joint

Second, the joining device must not only be strong itself, but it must not weaken the ends of the belt. Lace leather, even when skilfully applied, makes necessary holes of a size that reduces the cross section of the belt, and when bungingly applied cut into the belt very seriously. The various wire lacings do not cut anything from the belt, but they result in a series of perforations which make it easy for the end to be torn off, just as the bank checkbook makers perforate the checks, so that they may be readily detached. The various plate hooks distribute their load better over a larger area of belt, and are not so likely to tear out the belt.

Third, the joint must be smooth and even in its operation over the pulley, more especially at high speeds. A badly laced joint, or a plate hook, strikes the pulley with a hammer blow, and even a well laced joint makes itself heard and felt, all to the injury of the belt and its fastening, and to the machine of which it is a part. The wire lacings and fasteners are comparatively smooth in their operation, but the testing machine of The Leather Belting Exchange Foundation shows that there is a momentary slippage on the pulley as such a joint passes over it, and a consequent momentary reduction in power transmission.

Fourth, any successful method of fastening must be durable. Some changes are required while the belt is new and stretching to its place, but when once run-in the fastening should serve for a long time. Probably nothing is so annoying as to have to stop production to repair a belt joint. Lace leather, though long lived, wears out, and the metal fastenings crystallize and break, so that none of them have the same permanency as the belt.

The Endless Belt

The happy resources for all these difficulties is the readiness with which a leather belt may be made endless, and the operation is so simple as to bring it within the ability of every shop. Where the plant is large enough, some good mechanic, or some handy man with the mechanical instinct, should be placed in charge of the belts, or where the plant is not large enough for this, the foreman or engineer should take them in charge, and they soon will learn to do the work expeditiously and well. It is only necessary that the belt shall be properly fitted to its pulleys for length, and there shall be cut on each end the necessary bevel for the lap, and that it shall be cemented properly, and the cement permitted to dry. In the case of small belts, these usually may be cemented and thrown on the pulleys while they are moving slowly. With larger belts, it is necessary to use belt clamps, but these need add but little complication.

The tools required are as follows; a square, an ordinary spoke-shave, with a good edge for doing the rough cutting in shaping for bevel. A scraper for finishing this bevel to a smooth surface, and to make a fine point. Possibly some sandpaper to compensate for a poor scraper. A double-jacketted glue pot, with a brush. A couple of hard-wood blocks, with bolts and nuts, between which the joint may be placed and pressure applied, or a set of bench screws may be used for this purpose. A set of belt clamps of suitable size. Most all of these can be found in the plant, or a complete set of tools may be bought at small cost from one of the belting manufacturers, and most of them specify them in their catalogues, and they will supply also the necessary cement, at a small cost.

Joint Must Be Smooth

The requisites are that the two ends must be brought together perfectly square with each other, and that the faces of the joints must be perfectly smooth, and an even bevel from heel to point. If they are bumpy, and do not lay flat together, the cement will not stick properly. The latter must be applied hot, and well worked into the fibre of the leather, and pressure should be applied before the cement sets. In the absence of pressure, it will answer if the joint is well rubbed with a tool handle, or a smooth substance during the process of setting, though pressure is more desirable.

If it is desired to make a joint that will not be affected by dampness, it is necessary to use the waterproof belting cement, which can be obtained from any leather belting manufacturer. With this cement, it is necessary to size the learther before cementing. Give each part of the lap one, or better, two good coats of the cement, allowing each to dry before applying the next, then to cement these sized joints and bring the two faces of the joint together, and to apply pressure or rubbing as above described.

The leather belt, sufficiently run-in, and fitted to its job, and made endless in this manner, makes a permanent in-

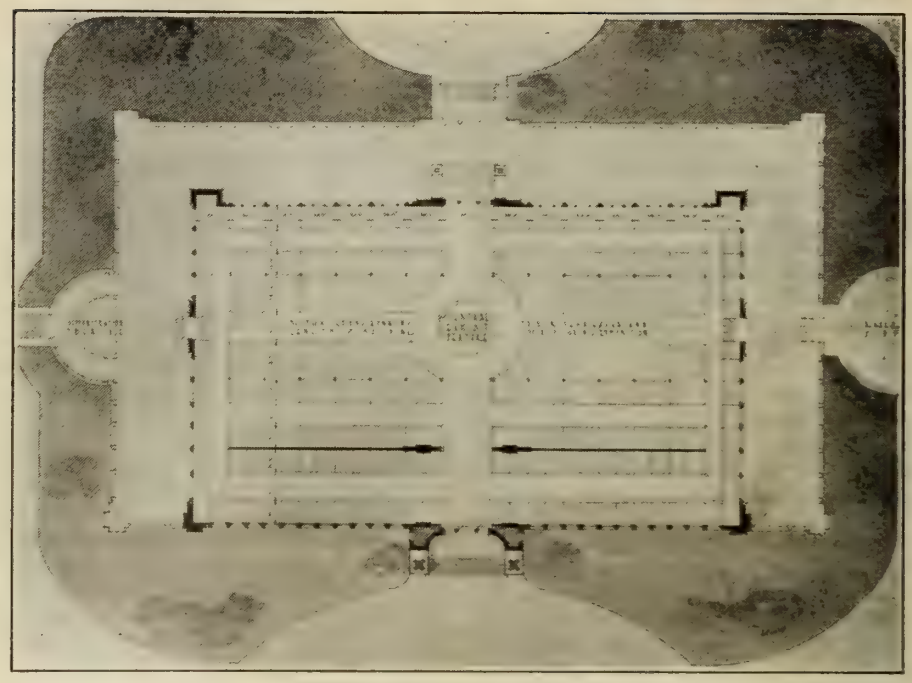
New Engineering Building For Exhibition

Machinery Displays to be Adequately Housed—To Be Self-Supporting on Space Lease Plan—Requirements of Industry Consulted



General Plan of New Engineering Building

AT LAST, plans are taking definite shape for the erection of an engineering building to take the place of old Machinery Hall at the Canadian National Exhibition in Toronto.

The movement looking to so desirable an object had its beginning in 1912, and gained headway until in 1914, the proposition was submitted to Toronto ratepayers, but owing to uncertainty of conditions, due largely to the outbreak of the war, it was voted down.

Buildings Self-Supporting

As in the case of all of the modern buildings at the Exhibition grounds, the funds are provided by the city, and the exhibitors of the industry represented are required to pay for display space at a rate that will provide revenue sufficient to ultimately cover the cost. The style of building is determined by the directors of the exhibition in consultation with the representatives of the industry concerned. Space rates will likely be in the neighbourhood of 90 cents per square foot.

In connection with the proposal to erect an engineering or machinery building that will do justice to Canadian industry, a representative committee of which T. A. Hollenrake of the A. R. Williams Co. is chairman, has not only had plans prepared for consideration, but has done much toward feeling out manufacturers in the matter of leasing spaces for a term of 10 years, which for all practical purposes is the limit generally proposed by Toronto City Council Already something like 20,000 ft. has been guaranteed, and this is regarded as a very satisfactory start.

It is proposed that the new building be located directly opposite the new eastern entrance to the Exhibition grounds. The illustration herewith shows it to be a most imposing structure and well in keeping with the general scheme

Architect's drawing of the new engineering building at The National Exhibition grounds, Toronto.

being worked out by the directorate to have buildings that will be creditable in every way to the reputation of the exhibition. It is hoped to have it ready for occupancy in 1923.

Adequate Floor Area

Of course, plans as prepared may be said to be tentative, but as proposed the building's dimensions will be 200 ft. by 400 ft. with a floor area of 121,000 sq. ft. The main display spaces as shown on the plan have a width of twenty-four ft., but it is understood that these are arranged in such a way that they may either be sub-divided or enlarged to meet requirements. The sketch shows provisions for a fifty-ton crane running the length of the building, a railroad track for unloading which will be depressed within the building so that it may be covered over while the exhibition is in progress. There is a large central space for special display, representative, say, of enterprise, such as electricity, and special areas are also provided for demonstration purposes. In short, every effort is being put firth to have the building so planned that it will meet the requirements of a strong industry.

Will Encourage Educative Displays

The old building has been most inadequate. The light was poor, spaces ill-arranged, and the areas insufficient for effective display. Its general appearance, moreover, was uninviting, and of recent years, representative firms, though admitting the advertising value of the exhibition, have remained away. In fact there are many such firms in the machinery industry who could use the entire building in a display of their own particular products.

Manufacturers will undoubtedly welcome the new proposal as one that will enable them to show to advantage the products of their industry. Such displays fall short of the mark if not highly educative, but it has been long felt that in old Machinery Hall this purpose has been sadly handicapped.

The plans of the exhibition directorate have in view the addition of 84 acres to their ground by 1945. The present area is 264 acres, so that these ambitions point to an ultimate layout of something like 350 acres, in which all important industries will have a distinctive segregation.

It is a thoroughly representative committee that has been chosen to co-operate with the Exhibition Board in working out details in connection with the proposed building. The members are: T. A. Hollindrake, chairman, A. R. Williams Co., Toronto; J. H. L. Patterson, Miller & Richards, Toronto; Wm. Robinson, P. B. Yates Machinery Co., Hamilton; C. A. Waterous, Waterous Engine Works, Brantford; C. F. Wheaton, Dodge Mfg. Co., Toronto; W. S. Hamilton, D. K. McLaren, Limited, Toronto; Alex. Goldie, Goldie & McCulloch Co., Galt; S. Gaskill, Lancashire Dynamo and Motor Co., Toronto; Wm. Inglis, John Inglis Co., Toronto; W. P. Dobson, Hydro-Electric Station, Toronto; John Crowley, Davis Bournonville, Toronto; F. M. Bawden, Bawden Machine Co., Toronto; W. S. Braden, Canadian Westinghouse Co., Toronto; J. . Blair, Alfred Herbert, Limited, Toronto; C. B. Hamilton, Hamilton Gear and Machine Co., Toronto; J. A. Ferguson, John Bertram & Sons Co., Limited, Toronto; J. P. Murray, Associate Director Canadian National Exhibition.

Direct Reading and Limit Snap Gauge Micrometer Calipers

A NEW departure in the design of micrometers has recently been introduced in the form of a micrometer that gives measurements directly in figures. This arrangement will no doubt appeal to many users, as there is always present the possibility of making an error in reading. As will be seen in Fig. 1, the readings are taken off directly and thus all chances of error are eliminated. Of course in the case of the skilled mechanic, tool maker, or inspector, who has had years of training in the use of the micrometer, rarely does a mistake occur in reading an instrument. There does exist, however, the fact that a certain mental calculation is necessary to transform the reading into a decimal expression. Now a first-class man who uses micrometers a great deal in his daily work will often find it necessary to use the instruments at times when his mind is centred on one or two matters of major importance. This pre-occupation would tend to distract him and make the actual interpretation of the reading occur under conditions not exactly ideal. In just such times as this, mistakes occur which may or may not have far reaching effect. In order to eliminate to the greatest possible extent the chance of human error, these micrometers were produced. The design is a simple compact combination of well-tested counting device with the micrometer. This counting device is so compactly designed and so centrally placed as to balance the micrometer nicely. To gain additional accuracy graduations are placed on the handle and barrel which enable extremely accurate readings to be taken, which serve as a check on the direct reading.

Limit Snap Gauge Micrometer

Probably the only real problem, and objection to the adoption of the limit snap gauge, was in cases where the production was limited and there was evidenced a thought that the expense was not warranted. In cases of small production it is readily admitted that the product is more readily and more economically controlled by standard measuring instruments than through the medium of gauges. There always arrives a point in an increasing production problem where standard measuring instruments become a more expensive method of control than that of gauges. As stated in our previous references to gauges the snap gauge was one of the commonest and most useful of gauges in general work. To meet the demand of an adjustable limit snap gauge for varying work produced in small quantities, and for the thousand and one other emergency demands for a gauge, the limit snap gauge micrometer has been developed. Fig. 2 shows a cut of this instrument. The field of application of the instrument is very large and it be used in many shops and on various operations where heretofore the expenses of limit snap gauges were considered too great to be borne by the job. The wide range of adjustment and the efficient lock all tend to make the application very wide. Thus it is not possible to attempt to describe the uses of this snap gauge micrometer, as one would run into very interesting applications at every turn. The uses of the instrument are almost self evident as simplicity is the keynote of the design.

Air Transformer Shows Remarkable Efficiency

New Meaning to the Term "Free Air"—Low Consumption of Compressed Air—Big Saving Effected—Strainer Retains All Dust and Dirt

By D. M. McLEAN, E.I.C.

REMARKABLE savings are being shown by a new device for blowing forge fires and similar purposes recently introduced in Canada. A tiny jet of high pressure air discharges into a bell mouth nozzle leading to the forge and induces a flow of air from the atmosphere into the nozzle where it mingles with the expanding jet and is propelled into the pipe leading to the forge, providing the proper volume of air at a suitable pressure for the purpose.

In present practice, in boiler shops, blacksmith shops, steel erection, ship yards and certain chemical and other processess, it is customary totake compressed air from the general supply line and throttlte it down to a pressure of a few ounces before it reaches the forge fire. In rivet heating, for example, the ordinary small portable forge will require about 45 cubic feet of free air per minute to blow the fire. To compress this to the initial pressure of 100 lbs. will take the expenditure of approximately 7½ horespower. In constant daily use, this may mean a yearly cost for air from one forge of at least $300.

With the new blower or air transformer, made by the Ingersoll-Rand, and described below, the consumption of compressed air from the supply line is less than 2 cubic feet of free air per minute, requiring practically one-third of a horespower, because the other 43 cubic feet required for the fire is drawn from the atmosphere. This represents a saving in dollars and cents per year per forge, other conditions being equal, of not less than $275 per forge. The tterm "free air," therefore, takes on a new and very important meaning.

The chart, Fig. 1, shows graphically the results of three tests of forges operating with and without the blower. The space between the upper and the lower curves indicates the greatly lessened drain upon the compressed air supply, and the consequent savings are expressed in percentages at the top of the cut.

Test No. 1 was taken with a slow fire, No. 2 with a fairly hot fire and No. 3 with an intense fire. These percentages may also be considered as expressing the efficiency of the blower under the varying conditions, and they emphasize unmistakably the futility of the common practice of compressing the required quantity of air to a pressure of 80 to 100 lbs. and then throttling it down for use at a pressure of a few ounces.

These tests were taken with partial needle valve openings and consequent reduced pressure on the jet nozzle. The results of tests with the blower connected to an orifice tank with low pressure nozzle on the outlet to furnish resistance to draft and measure the output are shown in Figs. 3 and 4.

Fig. 2 shows the general arrangement of the device. V is an ordinary needle valve regulating the flow of compressed air. In ordinary operation, one quarter of a turn usually provides sufficient air for the work. After passing through the strainer S which retains all dust and dirt which might clog the device, the air reaches the special nozzle N and is discharged into the bell mouth B which is connected to the forge.

The bell mouth is cast solid with the strainer chamber, and ample space is provided for access of atmosphere air as it is drawn into the bell mouth. The strainer may be easily blown out by removing the plug at the bottom of the chamber. Home-made blowers resembling this device have often been made up from pipe fittings, but cannot attain anything like the results reached by this

Working Pressure on Jet Nozzle lbs. per sq. inch	High Pressure Air Used C.F.F.A. per minute	Low Pressure in Inches of Water	Free Air Delivered C.F.M.	Per Cent. of Air Induced
5	.96	.29	18.3	94.8
10	1.36	.48	23.6	94.5

90	5.85	2.95	58.5	90.0
100	6.45	3.25	61.4	89.5

The resistance to flow or draft pressure required in an ordinary forge is somewhat less than for a nozzle of this size. With less resistance the flow is greater in volume. The working pressure on the jet is controlled by the needle valve and can be anything up to the full line pressure. In forge blowing the working pressure required is usually from 15 to 40 pounds and draft pressures of ½ in. to 1 in.

Working Pressure on Jet Nozzle lbs. per sq. inch	High Pressure Air Used C.F.F.A. per minute	Low Pressure in Inches of Water	Free Air Delivered C.F.M.	Per Cent. of Air Induced
5	.96	.31	12.15	92
10	1.36	.72	18.5	92.8
15	1.67	1.00	21.8	92.3
20	1.93	1.25	24.4	92.2

90	5.85	4.57	46.5	87.5
100	6.45	5.05	49.0	87

With a 1 in. orifice the New Jersey Blower develops pressure or draft in excess of ordinary requirements for blowing forges. When pressure or resistance against which the Blower delivers is increased, this is at the expense of volume and also reduces the percentage of free air induced. The normal outlet of the Blower is 1¼ inches, giving a greater volume at a little lower draft pressure.

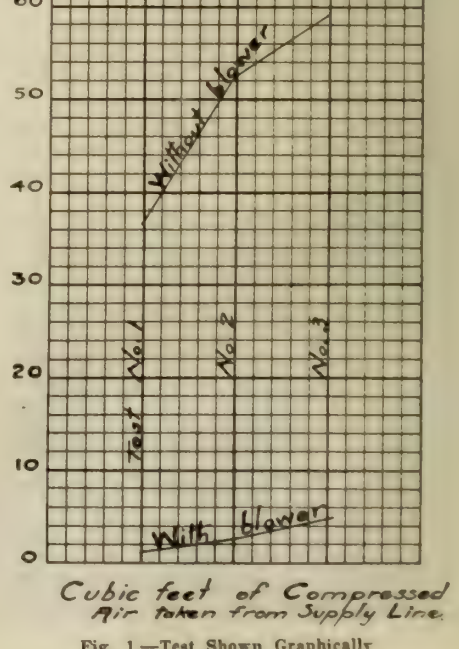

Fig. 1.—Test Shown Graphically

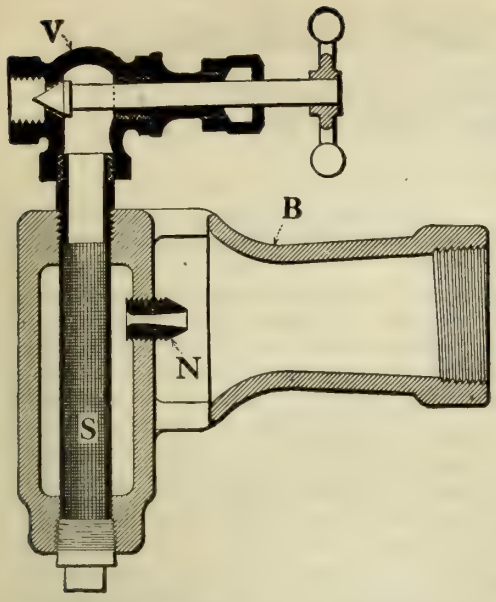

Fig. 2.—Cross section of new forge blower or "Air Transformer," showing arrangement of various parts.

specially designed appliance, proportioned and adjusted for the best possible work. The standard blower of this type is designed to deliver the air at a pressure of 4 inches of water, but higher pressures may be reached by the use of specially designed jet nozzles.

In the tests mentioned above the actual air pressure in the screen chamber below the needle valve was taken. This is the same as the working pressure on the jet nozzle. The cost of this device is such a small fraction of the saving it secures, it may be expected to have quite a wide application in its particular field.

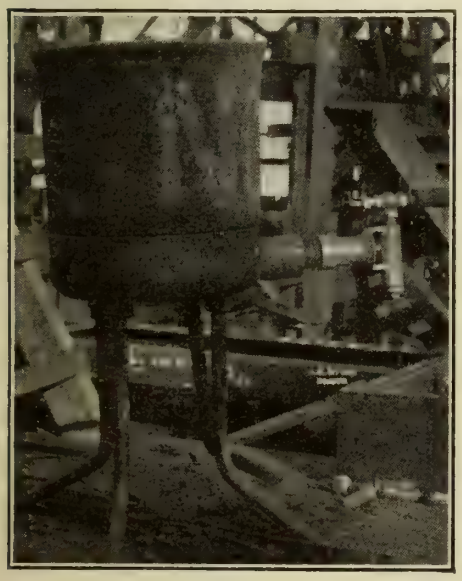

Fig. 5.—Installation of Blower

The great value of high speed steel is due to its quality of holding its hardness when cutting at a rate of speed and feed which heats the point of the tools to a red or higher heat, and also the greater length of time the tools will stand up to the work without regrinding.

CANADA'S EXPORT TRADE

The graph opposite shows the growth in Canada's foreign trade per head of population in comparison with that of the United Kingdom and the United States. Canada was in 1902 exporting products to the value of $28 per capita, as compared with $40 per capita for the United Kingdom and $15 per head for the United States. At the beginning of 1914, Canada had increased her ratio to $58 per head, an increase of 130 per cent. as compared with $70 per head in the United Kingdom, an increase of 75 per cent. and $24 per head in the United States, or 60 per cent. increase. The figures for 1921 show that Canada has not only held this increase but has passed the United Kingdom and now leads the world in value of exports per head of population, with $150 per capita as compared with $98 per head for the United Kingdom and $65 per head for the United States.

IRON AND STEEL FOR INDIA

That India is shaping up as a potential iron and steel market is evident from reports on recent British business in that part of the Empire. The Middlesborough correspondent of the Empire Mail makes the significant statement that British iron and steel is on the road to recovery. "We have shipped from Middlesborough alone nearly 100,000 tons of steel to India this year, and that is but a tithe of what she needs," said the principal of one big concern with world-wide connections. "Enormous quantities of railway material are wanted in India and the Far East. Big bridge works are contemplated and huge grain silos. Here there is work for our iron and steel works, and it only remains for our government to cast off the fetters from trade, and our workmen to sink their differences and make up their minds to give a fair day's work for a fair day's pay."

STEAM TURBINE LOCOMOTIVE

Ever since the steam turbine—which was invented by Sir Charles Parsons in Great Britain—proved its wonderful advantage on board ship and for electric power generation, railway engineers have been looking forward to the possibility of applying it to locomotives. A bold experiment was recently made by a leading British locomotive factory, which constructed a turbo-electric locomotive, now being tested on the rail. The main turbine on this locomotive drives an electric generator which supplies power to four motors arranged in two groups on the front and the rear respectively of the locomotive. Each of these motors is capable of developing 275 horse power. One of the novel features of this locomotive is the condenser, in which the steam tubes revolve in water at a slow speed. The makers claim that this locomotive gives considerable saving in both fuel and water compared with the existing types.

IMPORTANT POINTS

(Continued from Page 41)

stallation, requiring no further attention for a long time, when it may be necessary to "take it up" a little. When this must be done, open the old joint with a screw-driver point, make a new lap on one end, scrape the old cement off the other to get down to the fibre, and make the joint as before.

An endless joint on a leather belt meets all the requirements above mentioned. It is stronger than any lacing or metallic fastening, and as strong as any other part of the belt. It does not weaken the ends of the belt. It is smooth and even, and it will travel over the pulleys, even small pulleys, at high speeds without a jar, and it is durable, for, unless necessary to open the joint to shorten the belt, it will last as long as the belt itself. There is no loss of power, even momentarily, as the belt passes over the pulley.

With the same outfit, it is always possible to keep all the leather belts of the plant in perfect condition. The cementing down of a corner of a lap, or the insertion of a small new piece of leather, will indefinitely prolong the life of the belt. Or the belt can be lengthened by cementing a piece to one end, or if not heavy enough for its work, an additional ply can be cemented on it, or it can be cut down to narrower sizes.

BOOK REVIEW

The McGraw-Hill Book Co. has just issued a book entitled "Metal Cutting Tools," by A.L. DeLee, M. S., M. E. The purpose of the book is to bring before the reader the principles underlying the selection, design, maintenance, and the proper application of cutting tools, rather than a treatise on a variety of existing equipment. The book is prepared for the practical man as well as the student of science, and where mathematics are used they are applied in such a form as to be easily understood by the workman in the shop. Every class of metal cutting tool is given consideration and the construction and action of different shapes, together with the resultant strain and stresses are dealt with in detail, giving to the reader a thorough knowledge of the elements of design in the development of cutting tools. The book is 6 x 9, and contains 330 pages.

Edgar Allen & Co., Ltd., have recently published a most interesting handbook on the application and heat-treatment of their high-speed steels for milling cutters, reamers, bits, form and other cutting tools. It gives much information to users of high-speed steel in general and to machine tool users in particular.

Accidents never happen—they are caused.

Sit in judgment on yourself—are you as careful as you could be?

Important Developments in British Industries

New Combine of Large Engineering Firms—Business Secured From South America—Bridge Building in China—Labor Conditions Generally Improved

SPEAKING on the general outlook in the machinery and engineering trades in England, F. W. Field, H. M. trade commissioner at Toronto, says that the most promising feature of the past few weeks has been the settlement of the labor dispute in the shipbuilding trades.

"This settlement will undoubtedly have a beneficial effect on trade generally," remarks Mr. Field, "as it must lead to a reduction of labor costs. Certain work which has been diverted to continental yards on account of the dispute will henceforth be dealt with in that country and any new ships laid down will be completed at a lower cost.

"The engineering lock-out is still in effect, but conditions appear to be more favorable to an early settlement. This is emphasized by the fact that orders are still coming in with fair regularity for new construction as though the purchasers anticipate that the duration of the dispute would be short. In the meantime the suppliers of raw materials, such as iron and steel and non-ferrous metals, are in a position to supply all the requirements of the home and export trade.

The market in engineering goods and raw materials is inclined to be sensitive owing to the fact that it is dangerous to lay in large stocks of materials in case there should be a fall in prices. In these conditions overseas buyers are well advised to purchase through channels which are well placed to take advantage of these repeated variations in price. It will be understood that buying at advantageous prices cannot very well be undertaken by inexperienced or distant purchasers.

"The market in engineering goods and establishing economic relations between countries which have been separated by political and economic barriers for a long time. The degree of success achieved will doubtless lead to a general revival in the engineering trades, particularly and more especially in such trades as agricultural machinery and general development works. This will undoubtedly steady prices, in some cases perhaps on a higher level than at present, but generally at a lower level in view of the fact that large scale production usually leads to economy. The gradual readjustment of prices downwards based on cheaper raw material and lower wages costs appears to be continuing, and is the most promising side in connection with the future trade in export markets.

A New Combination

"An important development in the engineering industry is the formation of the British Power and Transport Finance Co., with an initial capital of a quarter of a million pounds. This company has been established for the purpose of combining the technical resources of several of the best known firms in order to investigate overseas engineering schemes and to provide the necessary finance where possible. The firms involved in the new combine are the following:—

Cammell Laird and Co.
Sir William Arrol and Co.
The English Electric Co.
The North British Locomotive Co.
John Brown and Co., and the Prudential Assurance Co.

The following constitute the board of directors of the new combine:—

Mr. W. L. Hichens, chairman of Cammell Laird and Co.

Sir John Hunter, managing director of Sir Wm. Arrol and Co.

Sir George May, Prudential Assurance Co.

Lord Meston, director of the English Electric Co.

Mr. P. J. Pybus, managing director of the English Electric Co.

Sir Hugh Reid, managing director of the North British Locomotive Co., and Mr. John Sampson, director of John Brown and Co.

"This formation has been prompted by the signs of trade revival and by the experience gained during the past two years, in which it was clearly demonstrated that individual British firms, while able to carry out work of the highest order on the lines in which they are interested, were definitely excluded from larger openings because of (1) lack of the necessary finance, (2) absence of arrangements for doing work other than that in which they were directly interested, and (3) the magnitude of some of the schemes.

"The new company have already got to work and it is known that they are interesting themselves in a number of contracts now open, particularly dock and harbor, and railway development schemes in South America. Confidence is felt in engineering circles that they will be able to secure a sufficient number of contracts to justify their existence.

Bridge, Dock and Harbor

"In these engineering lines firms have, since the end of last year, been doing very good business, and the more important concerns have now a number of useful contracts in hand. The Cleveland Bridge and Engineering Co., is, perhaps, the outstanding example, having secured a fair share of the world's business. Particularly might be mentioned the construction of the Menam Bridge in Siam and a number of railway bridges in the same country, while it is understood that the negotiations for the construction of the bridge across the Santa Lucia and that across the Magdalena River in Colombia are well advanced.

"S. Pearson and Sons are now at work on the bridge across the Yellow River in China, whilst they have also in hand the construction of bridges, the repair of canals, and the extension of docks and harbors in Belgium. They have, further, concluded a contract amounting to about two million pounds for the extension of the water supply of Belfast. The contract is expected to extend over seven years.

"Sir William Arrol & Co., have in hand a number of contracts in Argentine and Chile and are in negotiations with regard to the extensive scheme of dock and harbor construction on the Chilean Coast. They are competing strongly for the erection of the bridge across Sydney Harbor.

"The smaller firms are also well equipped with a number of bridges and similar classes of works, both at home and abroad.

Railway Rolling Stock

"Builders of locomotives, carriages, and wagons have been doing fairly well during the past two months. The North British Locomotive Co., William Beardmore and Co., Sir W. G. Armstrong Whitworth and Co., The Vulcan Foundry Co., and others have, it is understood, secured considerable contracts for the supply of locomotives to Roumania, whilst Kitson and Co., Airedale Foundry, Leeds, are engaged on eight new locomotives for the Palestine Railways. Colonial orders have helped considerably to make up the numbers required and the shops may be said to be assuming something like normal conditions.

"The Birmingham Railway Carriage and Wagon Co., are quite busy on stock both for home and foreign railways. The Metropolitan Carriage, Wagon and Finance Co., are supplying to the Palestine Railways four first and second class combined, six second-class, and nine third-class coaches together with four third-class and brake composite, two tri-composite and brake, and three luggage and postal brake carriages. The Birmingham company referred to above has its share of the Palestine orders in the form of 10 bogie first-class carriages.

"The Metropolitan Carriage, Wagon and Finance Co. is understood to have secured considerable orders for Russia, while the Leeds Forge Co. is engaged on 1,000 tank wagons for that country. Firms manufacturing permanent way material are well placed with their orders, having secured fairly large contracts in the face of foreign competition."

Practical Ideas From Practical Men

MAKING AUTO WHEELS

By Geo. Barrett

The automobile wheel to receive the most general application on all types of cars is that constructed with wooden spokes and known as the artillery wheel from the fact that it was originally designed for use on gun carriages.

The spokes are turned from a wooden billet A, the operation being performed on a special lathe and called club turning on account of the shape of the stock after it leaves the machine. The elliptical spokes are obtained by movable centres and a cam action, which moves the lathe heads in and out with respect to the cutters, to get the shape desired, shown at B.

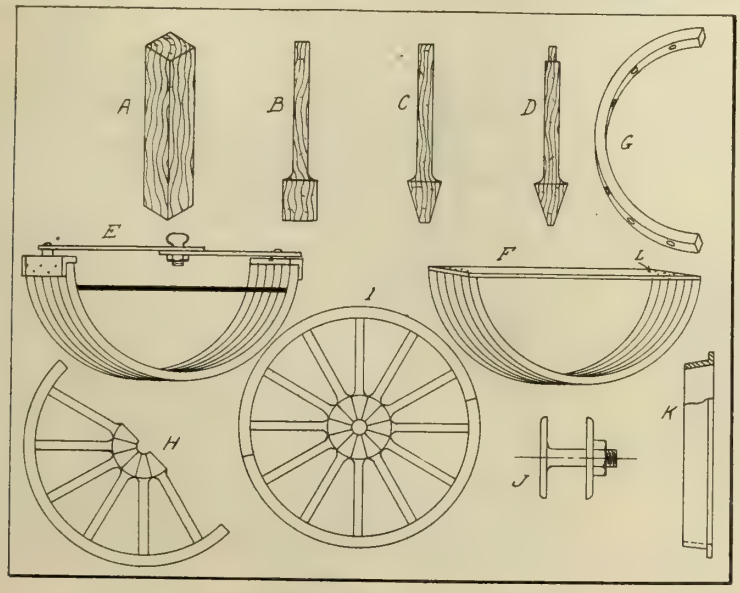
The next operation is mitering the large end as shown at C, which is performed by two saws set at the required angle, and afterwards finished correctly by two knives. The next step is to turn spokes tenon at upper end D to fit the wooden fellow or rim of wheel. This is done with a revolving hollow cutter set to correct diameter so as to have a pressed fit in rim after boring for spokes.

The fellows are made by bending wooden stock, previously cut to the desired length and thickness, and steamed for several hours, the bending being done on special machines. The stock is placed —6 in number—on a flat piece of sheet steel, and has two clamps which hold the bent wood against the spacer at E in order to secure the desired curvature. They are then placed in drying kilns for a considerable time. After removal the steel clamp is removed and pieces held by strips shown at F, and sawn and planed to correct form.

The next operation is drilling the fellows for the tenon of the spoke; this is done on a single purpose machine. A sanding machine is then used for chamfering inside between spokes, and afterwards the holes are spot faced for spoke bearing.

The first stage in assembling the wheels is shown at H. The spokes are driven into the fellows and after combining the two halves the wheel is placed in a hydraulic press which clamps the spokes and rim tightly together. The spokes are supported by a dummy hub as shown at G. The wheels are now ready for the steel rim and are laid on a special table where they are heated by gas flames sufficient to expand them so the wooden centre can be inserted and placed under a press to force the steel rim to its proper position on the fellow. The dummy hub is then removed.

Next operation is boring and facing for the hub. After holes are drilled and bolts put in, the assembled wheel is twisted for correct balance. The final operation is drilling and inserting dismountable rim bolts and clips.



Making Artillery Type of Auto Wheel

PUNCH AND DIE DIMENSIONS

G. L.

The question sometimes arises: "What is the relation between minimum punch diameter, clearance and thickness of stock?" One firm has found the following by experiment.

"Our usual practice is to make the clearance between punch and die about one-fifth the thickness of stock. If the stock is high carbon steel or thicker than the diameter of the punch, greater clearance is necessary. For light work such as sheet metal, a clearance between .002 in. and .005 in. is satisfactory. We find that for ordinary machine steel the minimum diameter of hole punched may equal the thickness of stock, on the average.

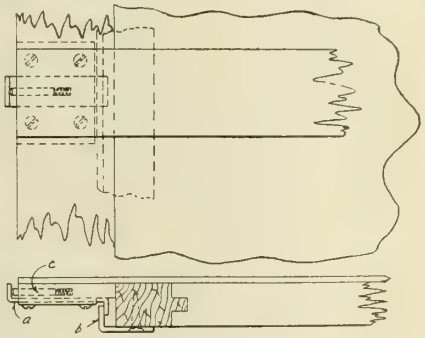
"In soft machine steel of about 10 per cent. carbon, we have cases where we regularly punch 9/32, 13/32 and 15/32 in. holes in ⅜, ½ or ⅝ in. stock respectively. This gives a ratio, hole to stock, of about 75 to 1.

"In hard spring steel of .60 to .70 per cent. carbon and .90 to 1.10 per cent. Manganese, we punch a 9-16 in. hole in 7/16 in. stock as received from the mills, the average life of the punch being about 100 holes. On attempting to punch a ½ in. hole in the same piece, the usual result was a broken punch. Our experience also shows that 13/32 in. is a safe minimum diameter for holes in 5/16 in. stock of this steel, as it allows a good life to the punches. This gives a ratio, hole to stock, of about 1.25 to 1."

SELF ALIGNING T-SQUARE

By N. F. P.

The accompanying sketch shows a T-square with an attachment for maintaining alignment at all times when in use. The slide (a) being kept out by the spring plunger (c) against the angle



Self aligning T-square

strip (b) holds the T-square in position which is easily released by a slight pressure of the hand. The slide is retained by a small plate as shown.

HOW TO WEIGH ATTACHED IRREGULAR PARTS

By W. F. Schaphorst

Occasionally it is desired to know the weight of some part on a machine, but which cannot be detached easily for weighing and it is too irregular to compute with ease. In such case the weight can be found indirectly by weighing the water displaced by the part, if the part projects in such a way that it can be made to displace water. For example, the writer once had to determine the weight of a flywheel governor weight, which was made of cast iron, and which could not be detached without removing the governor from the engine.

We turned the flywheel to such a

position that the weight was at its extreme low point. We then procured a rectangular sheet metal vessel and filled it with water. We weighed the vessel when it contained as much water as could be held in it. Then the vessel of water was carried over to the engine and raised so as to envelop the weighted end. Water was displaced, of course, but that is what was wanted. The vessel was raised until the water level cut the governor arm.

The vessel was again weighed; this time with the remaining water. The weight of the governor end was then computed in this manner: the first weight was 45.5 lbs. and the second was 39.5 lbs. The weight of the water displaced was therefore:

45.5—39.25=6.25 lbs.

Now to compute the weight of the cast iron that displaced the water all that is necessary is to multiply by the specific gravity of cast iron which is 7.207 or:

6.25 x 7.207=45 lbs.

The remainder of the arm was of rectangular cross-section whose weight was very easy to compute on this basis of 0.26 lbs. per cubic inch, which is the weight of cast iron. In case other metal parts are to be weighed in this manner here are the specific gravities of metals most commonly used in mechanical constructions:

Cast iron	7.07
Wrought iron	7.78
Soft steel	7.833
Steel castings	7.917
Cast aluminum	2.60

Should it be desired to know the volume of the piece of metal in cubic inches divide the difference in weight (which is equal to the weight of the displaced water) by .0362. The result is the volume of the part in cubic inches. The latter test will come in handy for finding the volume of any irregular substance that can be submerged in water without harm or without any absorption of water. Or, should one wish to find the specific gravity of coal, brick, rock, etc., this method reversed, will serve the purpose. Weigh the rock, say, and then weigh the displaced water (which can be done by subtraction as already explained). Divide the former by the latter and the quotient is the specific gravity of the rock or other substance.

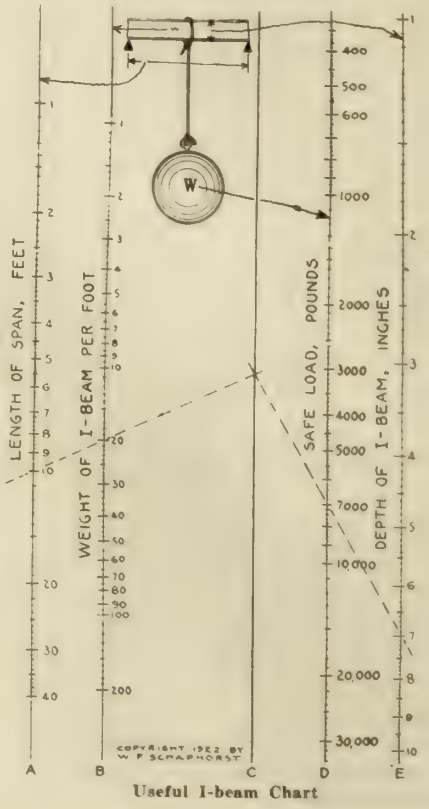
A USEFUL I-BEAM CHART

By W. F. Schaphorst

Here is an I-beam chart that tells all about I-beams almost at a glance. It is much quicker than a table for solving many problems such as are met frequently. The I-beam is the lightest and most economical steel beam for most purposes. Inasmuch as a concentrated load, as shown in the sketch, represents the very worst conditions, requiring the largest beam for the given load, this chart is based upon such loads for the sake of safety. The wavy arrow lines running from the sketch to the vertical chart lines show at a glance just what each chart column means. Thus, column A gives the length of the span in feet and includes all lengths from 1 ft. to 4 ft. Column B gives the weight of the I-beam in lb. per ft. and includes all weights from 1 lb. to 200 lb. Column D gives the safe load of the I-beam and varies from 400 to 30,000 pounds. Column E gives depths of beams in inches from 1 to 10 inches.

For example, to show how the chart is used, let us suppose that a weight of 4,000 pounds must be lifted. A 7-in. I-beam weighing 240 pounds is available. It is 12 ft. long and therefore weighs 20 lb. per ft. The minimum distance between supports that can be obtained for the lifting operation is 10 ft. Is the I-beam strong enough to lift the 4 000 lb. load?

The dotted lines drawn across the chart show how the problem is solved by means of the chart. Run a straight line through the 10 ft. (Column A) and the 20 lb. (Column B) and locate the intersection in Column C. Then from the intersection in Column C run over to the 7-in. (Column E.) The intersection through Column D shows that the I-beam will support 7,000 pounds. Since the load to be lifted is only 4,000 pounds the beam is amply strong. In fact, the reader can easily find by applying the chart that a 4-in. I-beam, all other conditions being the same, would safely support the load of 4,000 pounds. Similarly, it is easy to ascertain the maximum allowable span when the factors in Columns B, D and E are known. Or, the necessary weight per ft. of I-beam may be determined when the factors in Colums A, D and E are known. Lastly, the depth of beam can be determined when the factors in Columns A, B and D are known. For loads that are "uniformly distributed"—not concentrated—the safe loads in Column D may be multiplied by two. Thus, the above described beam will support a uniformly distributed load of 14,000 lbs. or 1,400 lbs. per running foot.



Useful I-beam Chart

HINTS TO CHECKERS

I. N. B.

Before turning finished drawings over to the production department, it is very important to make certain of the accuracy of the different dimensions and the general information included on the prints. The following list of questions has been compiled to aid checkers in eliminating the possibility of error in the making of the product:

1.—Is the size of the sheet correct?
2.—Is the layout of the model correct?
3.—Can fixture be loaded and unloaded without interference?
4.—Can the fixture be assembled?
5.—Do figures "tie-up?"
6.—Are there enough dimensions on each piece?
7.—Are the dimensions to scale?
8.—Are dimensions not to scale underlined?
9.—Are finish marks on drawing?
10.—Have grind notes and other necessary notes been included?
11.—Does fixture fit the machine, and have bolt holes been provided?
12.—Is stock list and bill of materials on the drawing?
13.—Spot for marking?
14.—Have Title No., Part No., Pattern No., Order No. and Sheet No. been en?
15.—Has provision been made for gauging on milling fixture?
16.—Is pattern constructed in the simplest manner?
17.—If a chucking ficture, is it counterweighted?
18.—Don't be in a hurry—the time spent in checking may prevent loss of time in the tool room if hurriedly done. (Remember—the onus rests on you.)
19.—When you have checked a drawing always feel that there can be no come-back.

TAPPING CAST IRON

In answering a query as to whether a lubricant should be used when tapping cast iron with 1½ in. to 3½ in. collapsing taps, Threads recommends the following solution: 40 gal. of water, 10 gal. of mineral lard oil, 2½ pounds of soda ash (exactly), and 10 ounces of borax.

Take a barrel of about 50 gal. capacity. Tap at the bottom for spigot. Weigh the 2½ pounds of soda ash (caustic soda or caustic potash will not do). Thoroughly dissolve this with ten ounces of borax in a bucket of hot water. Place in the mixing barrel and add water until barrel is three-quarters full. After agitating this mixture of water and alkali, allow it to stand at least 30 minutes. Then add the ten gallons of mineral lard oil.

New Things in Shop Equipment

BALL BEARING TOOL GRINDER

A ball bearing tool grinder has recently been developed and placed on the market. The grinder is furnished with a floor stand but may be provided with the necessary offset if it is desired to bolt the machine to a post, or a plate can be furnished when being fastened to a bench. Fafnir ball bearings are used in mounting the spindle. The spindle can be driven direct by a belt attached to the line shaft, so that it is not necessary to start and stop it each time the grinder is used. All necessary tool rests, water pots, etc., are furnished with the machine. This grinder is manufactured by the Fafnir Bearing Co., of New Britain, Conn.

NEW DESIGN DIFFERENTIAL CHUCK

A wrenchless chuck for turret and engine lathes has recently been developed and placed on the market. The scroll-plate is made heavier and thicker to allow of cutting air internal gear on the face instead of the usual practice of bevel gears. The scroll-plate has its bearing on the outer edge of chuck body and not on the smaller bore diameter, giving added rigidity.

Directly back of the scroll-plate in the assembled chuck is an annular steel ring, attached to the body of the chuck as described later. Upon the inner circumference of the ring are cut the teeth of an internal gear similar to the one in the scroll-plate but slightly larger in pitch diameter. This ring is called the "backing gear." Turning freely upon a large ball bearing mounted on the hub of the chuck is a ring, known as the "handwheel," of the same outer diameter as the chuck body. This wheel may be seen in Fig. 1, where it appears as the knurled portion of body, and separately in Fig. 2 with the backing gear and differential pinions in the respective places. Five pairs of pinions are mounted on studs shouldered into the inner face of the web of the handwheel. Of each pair, one pinion is slightly smaller in pitch diameter than its mate and meshes with the internal gear of the scroll-plate, while the larger one meshes with the backing gear. The two pinions of each pair are pinned together as one piece, the entire mechanism thus forming in effect an epicyclic train.

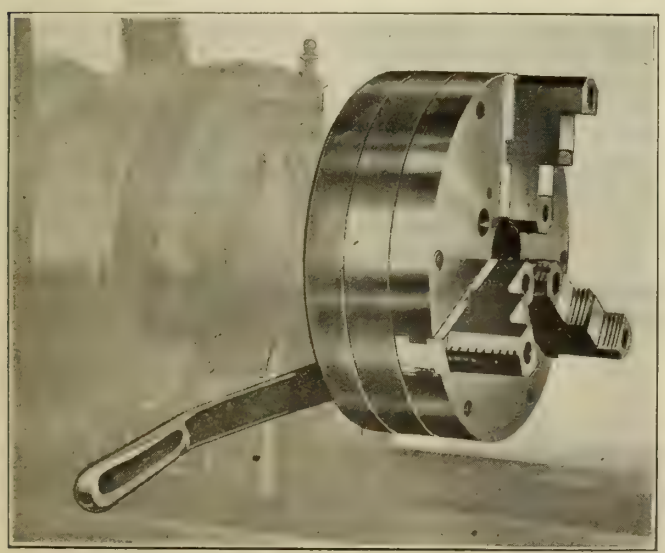
Because of the differential ratio, the internal gear that is part of the scroll-plate will turn slowly backward with relation to the stationary chuck body. Similarly, when the chuck is running forward with the lathe, if the hand is pressed upon the knurled part of the handwheel and its rotative movement stopped, the differential action of the epicyclic train will cause the scroll-plate to creep slowly ahead of the revolving chuck and thus close the jaws. This differential action may be made in any desired ratio. In practice, it has been found desirable to make it about 9 to 1, causing the chuck jaws to move radially 1-32 in. for each full revolution of the handwheel upon the chuck body. When mounted upon a machine, as a lathe, turret, or screw machine, a lever and brake are supplied to be attached to the headstock, thus providing means by which the pressure may be applied to hold the handwheel stationary while the rotation of the chuck automatically closes the jaws upon the work.

The backing gear is held to the chuck body by studs entering short curved slots upon its periphery in such manner as to permit a certain amount of lost motion or "backlash" in the mechanism. Thus a quick forward movement of the handwheel will deliver a hammer blow upon the train, and will effectively release the most obstinate grip. This rocking movement of the handwheel may be repeated, if necessary, until the chuck releases, when the wheel will spin rapidly forward without material resistance. Except for the manner of operating it, the chuck is the same as the standard steel-bodied Horton chucks the jaws being interchangeable.

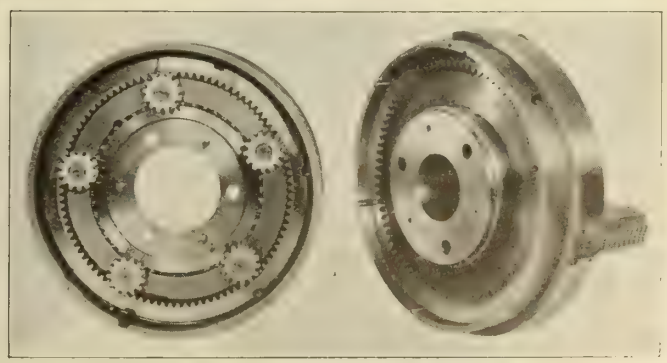
All moving parts are mounted on ball bearings, permitting of easy operation and rapid adjustment of the jaws to any desired position. The chucks are made in the 13 in. size and will also be manufactured in 9 in. and 16½ in. They are made by the E. Horton and Son Co., Windsor Locks, Conn.

SELF-ALIGNING BALL-BEARING PILLOW BLOCK

The essential features of a pillow block that has just been placed on the market are the double ball bearing hanger box and the self aligning pillow block. Both the end and radial thrust is taken by the balls. The bearing automatically aligns to compensate for any variation between the bed on which it rests and the position of the shaft. The inner ring is made very wide, in order to give the bearing a firm seat on the shaft and to afford a greater support to it. Special provision is made for preventing the escape of lubricant or the entrance of dirt. The block has no bolts, screws, or adjustments. It is secured endwise on the shaft by the means of two collars fitted with set screws. These collars have lugs which engage corresponding slots cut in the wide inner ring of the ball bearing. These pillow blocks may be easily installed. The spherical seat in the pillow block and the ball on the box permits the whole unit to align with the shaft. These pillow blocks are manufactured by the Fafnir Bearing Co. of New Britain, Conn.



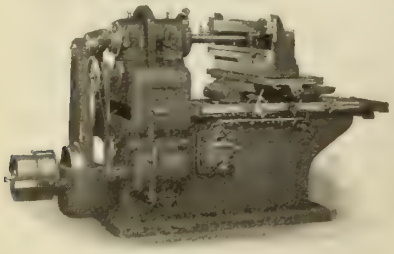
New design wrenchless chuck.



Internal view of differential gearing.

CYLINDER GRINDING MACHINE

A new design of cylinder grinding machine has just been placed on the market. A special feature of construction is the hydraulic drive for the main table, oil being used as the operating medium. The operator can reverse the table at any desired point without shock or noise. In addition to the vertical adjustment that it is possible to get with the universal locating jig the cross-slide table can be raised and lowered sufficient to take care of any vertical adjustment that may be desired by the operator after the block is strapped to



Heald Cylinder Grinder.

the jig. This is obtained by two inclined slides between the main table and the cross slide. The base of the machine is of ample dimensions to permit of undue overhand on either side, when castings with four or six cylinders are being ground. The main drive shaft is mounted on ball bearings and driven direct from the main line. The cross slide table has an adjustment of 28 in. Hole to hole setting is obtained by means of micrometer stops. The cross slide table has a vertical adjustment of 5/16 in. obtained by means of two inclined slides.

The grinding head and feeding arrangement for the eccentric are of similar design to which has been used so successfully for over 17 years, the locating head being made up of two eccentrics, one within the other, giving the grinding spindle a sort of planetary adjustment for accurately feeding the wheel to the work. There are three speeds to the eccentric, controlled by a conveniently located lever.

The grinding spindle is driven from the main drive shaft through a flexible idler which maintains uniform belt tension at all times and gives a very satisfactory driving arrangement. The spindle is hardened, ground, and runs in a solid taper bronze bearing at the wheel end, with a self-aligning ball-bearing at the pulley end. It is fitted with interchangeable pulleys, to give different speeds to the grinding wheels, so the operator can always obtain exactly the right speed, whether using large or small wheels for the work in hand.

For regrinding shops and for those who desire it, we are in a position to furnish a universal quick locating jig having a capacity of 38 in. which will take care of all styles and sizes of blocs used with standard makes of cars. It is made up of two extra heavy bars bolted to the face of the angle iron. These can be adjusted for various size blocs so that when in position the center of the holes will be the correct height for the wheel to enter. It is a great time-saver where there is a large variety of sizes and styles of blocks, each requiring a different set-up. A bulletin fully explaining this jig will be sent upon request. This grinder is made by the Heald Machine Co., Worcester, Mass.

INDUSTRIAL LOCOMOTIVE

A gasoline driven industrial locomotive has recently been placed on the market. This unit is intended for general hauling around industrial plants and for road construction. The frame and running gear are similar to other locomotives constructed by the same company. The motor is of 18 h.p. and has four cylinders. All parts of the mechanism are readily accessible but are entirely enclosed to give protection. The axles are driven from a jack shaft by means of roller chains, and the clutch is located in the fly wheel of the motor. The locomotive is constructed either with steel or cast iron wheels. The locomotive operates on a gauge of 24 in. or wider, and has a wheel base of 34 in. It operates at a maximum speed of 8 miles per hour and the track weight is about 4,000 lbs. These locomotives are manufactured by the Atlas Car and Manufacturing Co., of Cleveland, O.

NEW REX MICROMETER

Of particular interest to mechanics, tool makers, manufacturers and every user of measuring instruments, is the new line of Rex Micrometers, which afford a high grade precision tool at a low price. This tool is furnished for either English or Metric measure and includes 24 different sizes of micrometers to take measurements up to 24 inches, or 600 mm. These micrometers are regularly furnished with a clamp ring which clamps the spindle and preserves the setting. A feature of these micrometers is the rectangular shape of the frames which can be seen from the illustration. These frames give greater measuring capacity than frames of the circular type. Holes are used in the larger sizes to lighten the frames. The anvil, spindle, and other parts of this Rex line are similar to the parts of the regular Brown and Sharpe micrometers and means are provided for adjustment for wear of measuring surfaces and screw. The cut shows the Rex No. 11, 1 inch micrometer caliper without clamp ring which lists at $6.25 In the larger sizes, Rex micrometers are furnished in finished wooden cases. These cases are substantially made, and afford a good place to keep the tool as well as to protect it. While the price of these micrometers is low, their accuracy is carefully held to the highest standard. This Rex line makes available highly accurate measuring instruments at a low price either singly or in sets. These micrometers are made by the Brown and Sharpe Mfg. Co., Providence, R. I. (see cut).

REAMER HOLDER FOR LATHES AND SCREW MACHINES

An appliance for holding reamers in lathes and screw machines has recently been placed on the market. The holder is not of the floating type but a bushing or adapter is provided and suitably applied on the part of the lathe on which the holder is employed. When used on a turret the hole is first bored and then chamfered a short distance and reamed to provide the proper bearing for the centre plug, the cone-faced entering plug is advanced to the work and while held firmly in position the face plate which holds the adapter is firmly secured by means of screws. When the face plate is properly aligned the turret is taken away and the folding leaf inserted in its place. This assures that the reamer will be properly held in alignment with the work being reamed. The shanks of the reamer are so designed that they may be passed completely through the holder if desired. The various sizes of adapters are interchangeable. The holes in the adapters are interchangeable. The holes in the adapter may be made to suit the reamers that are being used. This device is manufactured by the Marvin and Casler Co., Canastota, N. Y.

ARE RUNNING CLOSE TO NORMAL

The Eclipse Machine Co., Elmira, New York, have a Canadian plant at Walkerville, Ont. Their line consists of the manufacture of Eclipse Bendix Drives, which are used as standard equipment and starting means on internal combustion of gasoline engines taking in the various lines of automobiles, both pleasure and commercial lines, aviation motors, marine engines, and motors for pumping or other power needed applications.

Industry Demands the Best

DO MANUFACTURERS sometimes overlook the dividend possibilities of their own enterprises? Profitable operation is, above all, the definite object of industrial effort, but it frequently occurs that, for want of better equipment, an otherwise efficient organization may be short of success. Instances are known where business men, disregarding an element that made for weakness, have shown preference for investment in channels that seemed to promise a better return than that from which they may be obtaining their bread and butter. In other words, they are willing that other men should handle their capital for them, and in an enterprise on which they may have the most meagre knowledge. To make money is desirable, but the best concentration and the best equipment is first essential for the success of the undertaking in which a manufacturer is engaged. If an organization is functioning properly in the scheme of things, it should be the most dependable source of profit. Old and dilapidated equipment and antiquated methods will hardly do under modern conditions.

In his day and generation, Andrew Carnegie said many wise things, and misdirected investment by business men must have come under his observation. In his autobiography he says:

"It is surprising how few men appreciate the enormous dividends derivable from investment in their own business. There is scarcely a manufacturer in the world who has not in his works some machinery that should be thrown out and replaced by improved appliances; or who does not for the want of additional machinery or new methods lose more than sufficient to pay the largest dividend obtainable by investment beyond his own domain. And yet most business men whom I have known invest in bank shares and in far-away enterprises, while the true gold mine lies right in their own factories."

Germany Under Economic Pressure

ACCORDING to reports coming from Germany, the fear that competition from that country would become more or less of a menace to profitable operation in certain branches of industrial activity, seems to have been hardly worth while. The trend of economic law seems to point to troublous times ahead. The boom is still on, but the rise in prices of basic materials and the increasing scarcity of money for industrial investments are among the factors that point to difficulty for the not far distant future. Moreover the cost of living for Germany has reached a point many times higher than that of pre-war levels, and at the same time the standard of living is said to be lower. Nor does it require a close observer to note the development of the strike fever. In fact in South Germany, the home of the metal industry, there were many weeks of inactivity while capital and labor fought over a difference of two hours in the working day. A more or less unsatisfactory compromise was the result. Further, it now becomes evident that until Russia has solved her internal problems, business cannot be developed with any degree of confidence in that quarter, and this in spite of any agreement entered into between the two countries during the Genoa conference. In short, that day seems to be fast approaching when inevitable economic pressure will bring German products to the level of world markets and hence more and more within the direct influence of international competitive conditions.

The Freight Rate Reduction

ANOTHER STEP in the somewhat delicate but necessary process of reducing freight rates on basic commodities, has been announced by the Board of Railway Commissioners. The change, effective Aug. 1, means a further decrease of 7½% on the original increase ordered in 1920 of 40% in the East and 35% in the West. What will now remain of this increase will amount to 12½% in Western Canada and 17½% in Eastern Canada. The Crow's Nest Pass agreement on grain and flour has been reinstated, certain arbitraries adjusted, and all increases on coal, other than anthracite and coal from the head of the lakes Westward have been rescinded. Thus the order of the Board seems to make freight rate reduction a matter of unanimity in U. S. and Canada. The Interstate Commerce Commission ordered a reduction of 10 per cent. on all commodities. This became effective July 1.

The decreases announced by the Board represent a loss in revenue to the two chief carriers of eleven millions each. Whatever the general opinion may be as to the extent to which the reduction will meet the requirements of brisker business, or in what form the twenty-two millions will eventually help the pockets of the consumer, the Railway Board seems to have given serious consideration to reports of traffic earnings of Canadian carriers. For the first five months of the year, these have shown serious declines as compared with last year.

In the steel industry, the reduction in freight rates seems to be regarded as an item that can be applied by way of relief in operation costs, rather than one that can be passed on, at once, to the consumer. As regards import business, there are those who feel that there is also a danger of the decrease being offset by the exchange rate. As a straight decrease, however, it represents a saving of $22.80 on a car of steel say from Pittsburgh. The rate at present is $7.60 per ton or $304 on a 40-ton carload. The saving will, of course, benefit the large purchaser most. The opinion among jobbers and manufacturers' agents is, therefore, that the decrease will hardly benefit the ultimate consumer as largely or as quickly as he has been led to suppose. The absorption of such an item in the different processes from raw material to its final consumption is an easy matter especially in a market that seems to be struggling upward through a very cautious industrial revival.

Increased Production in Steel Industry

Mills Are Well Sold Up—Prospect of Continued Activity During Autumn—Consumption Increased 27 Per Cent.—Prices Continue Firm—Some Advances Predicted—Railroads Appear in Market

MILLS MAY ADOPT CONSERVATIVE POLICY

STEEL markets are developing interesting features. A spirit of cautious selling is developing. Reports from Fittsburg indicate that mills could dispose of large tonnages if they were willing to accept on late year contracts. Mills are well sold up for the next two months, and although there is no change in prices to speak of, it is predicted that they are on the way. This is not altogether due to the coal strike. The demand will undoubtedly continue in strength during the latter part of the year, and it is inevitable that there should be a movement in the direction of more profitable operation than has been the case for the past six months.

To date production of steel ingots shows, for the first six months of 1922, an increase of six million tons over the same period last year. It is assumed that there has been some movement toward the replenishing of stocks that were liquidated last year, and that consumption has had a very material increase, say 27 per cent. If these factors are taking care of the enormous increase in production then there can be no weakness in the fundamental situation. If, on the other hand, consumption does not measure up to the increases in production trouble may ensue, such as a buyers' panic, next Autumn. It is not improbable therefore that some attempt will be made to hold prices at levels, at least, that cannot be criticized.

It is doubtful, after all, if the ending of the coal strike will bring a heavier demand for steel. Experience has pretty well established the fact that buying is keenest in lines of threatened scarcity and inclined to lethargy when supply is readily available.

Demand for building materials seems to be well maintained. Reports indicate that some very large tonnages are going forward to the mills for steel and plate.

Pig iron markets, though active, remain unchanged so far as prices are concerned. There are good supplies on hand, and the improvement in the foundry business will account for some increases in consumption. The decrease in freight rates of 7½ per cent. will be welcomed more as a factor tending to ease the load of operation, rather than one that can at present be passed on at once to the consumer.

An upward movement continues in steel and iron bars. In fact in some quarters, this advance is considered long over due and it is predicted that within the week there will be an advance to 3.15.

Non-ferrous metal markets show little marked activity. Some easing developed in electrolytic copper and castings copper, but this is considered more in the light of a fluctuation than indicating a decided tendency.

Machine tools are inactive though there seems to be an undertone of optimism that general conditions cannot continue an improvement, without a kindred showing in the matter of equipment. It is regarded by some, as probable, that if industry displayed a tendency toward a strong recovery and inquiry for machinery developed, a temporary easing of prices might be made by way of encouragement.

Small tools and supplies are in continued better demand, and the movement seems a general one, and not due to marked requirements in any one department of industry, although activities in agricultural implement and motor car manufactures are showing a much better tone.

Toronto

GENERAL firmness marks the Toronto metal market this week, the tendency in this direction being more pronounced in some quarters than was the case one week ago. If one will take, as an exampie, the situation in steel and iron bars, a decided upturn is regarded as inevitable. In fact an announcement of increases from the mills is momentarily expected. "It has to come," was the comment of one jobber. "Prices have been too low. There must be a normal spread as between mill and distribution prices. Our minimum price to-day is $3.00; next week we will probably have to say to you that it is $3.15. Mills can no longer be expected to operate below cost." In other quarters the comment was of a similar character. Price tendencies are upwards. General conditions are steadily improving. "The situation is immeasurably better than it was four months ago," remarked a jobber who generally inclines to a conservative view. "To-day, I would repeat what they used to say prior to the war, 'there is no crisis.' We seem to have come through the worst of it. Given a settlement of the coal strike and I will say that the outlook would be exceptionally encouraging."

Freight rate reductions effective Aug. 1 are regarded as a help toward stability. While the decrease may not seem important, it is a case where every little bit helps. For example, the rate between Pittsburg and Toronto is 38 cents or $7.60 per net ton. The rate on a forty-ton car would therefore be $304. As applied to this, the 7½% reduction would amount to $22.80 the car, not much in itself, but important enough to the large shipper. Immediate effect on prices, however, seems out of the question. Exchange rates have shown a tendency to move upward. Steel mills carry at least six months' supply of basic materials, and would appear to have been operating at such figures as would make the freight rate reduction welcome to them as a particular measure of relief in a more or less unprofitable situation.

It is regarded as a good sign that the railways are again making their appearance as buyers. The Algoma Steel Corporation and Nova Scotia Steel Co. are reported to have received large orders for rails and other track supplies. Favorable crop reports are being received from the West and this will undoubtedly account in considerable degree for slightly improved activity among agricultural implement plants.

Iron and Steel Bars:—The prices given herewith indicate the tendency toward stiffer prices in iron and steel bars. Even for small shapes prices are stiffening, and it is here that some dealers declare there should be a more marked boost than for regular sizes, as they represent an accommodation and one that is not altogether beyond the factor of additional expense. In some quarters there is a determined undertone indicating that the boost is somewhat overdue:

Iron bars	2 90 to 3 15
Steel bars	2 90 to 3 15
Reinforcing bars	2.90 to 3 15
Steel hoops	4 00
Tire steel	3 15
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in base	3 50
Small shapes	3 15
Sheets, black, No. 28	5 00
Sheets, blue ann., No. 10	4 00
Canada plates, dull, 52 sheets	6 00
Canada plates, all bright	6 00
Galvanized Sheets, No. 28	6 00

Scrap metal markets report no change so far as prices are concerned, but the feeling is better, as reflecting the general improvement in business. There is still a great deal of what is called "gun metal" copper and brass coming in from the Old Country. This is, as a rule, very carefully graded, and percentages are good.

Copper, light per 100 lbs.	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper Wire	11 00
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	4 85
Light brass	3 50
Medium brass	4 50
Scrap zinc	4 00
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	11 00
Axles (wrought iron)	16 00
Rails (scrap)	11 00
Malleable	11 00
No. 1 machine cast iron	16 00
Pipe, wrought	6 00
Car wheel	16 00
Steel axles	15 00

In the non-ferrous department, copper and brass products are reported as showing strength. An authority ascribes this tendency to several causes. The heavy tonnages left over from the war have been about absorbed, production has improved and Europe is said to be doing a little buying. In the basic non-ferrous metals, there was a little weakness apparent during the week-end. New York prices eased slightly. Electrolytic copper at $16.75 and castings copper at $16.50, are the more important items. Here, too, railways are buying more, and doing it direct, rather than through the large jobbers, thus saving one tax item.

Lake Copper	17 00
Electric Copper	16 75
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	6 75
Aluminum	26 00

Machine tools are reported as being the one black spot in the rising sun of industrial improvement. Dealers and manufacturers declare there is practically no demand for new equipment, except in the woodworking machinery line. This shows an improvement, explained by activity in the lumbering and furniture industries. The feeling is optimistic however. An upturn in business, it is felt, should create a demand for the best that the market has and there are those who say that such a development would be met, temporarily, at least, by reduction in prices.

Small tools and supplies are figuring in a better demand. The manufacture of radio equipment, the motor car and agricultural implement industries are regarded as three important factors in this section.

There seems to be an undertone in the machinery market that conditions are going to move slowly, but steadily, in the right direction during the next six months. It may be difficult to explain by facts and figures, but the feeling is there.

Due to a rise in the price of crude oil, an increase is announced of one cent in Royalite and Polarine, and of 1½ cents in premier gasoline.

Castor Machine oil, per lb.	34½
Royalite, per gal., bulk	0 20
Palacine	0 23
Machine oil, per gal.	33 00
Black oil, per gal	17 50
Cylinder oil, Capital	61 50
Petroleum fuel oil bbls., net	10 80
Pure turp., single bbls. gal.	1 40
Linseed oil, raw, single bbls.	1 15
Premier gasoline	35½

Montreal

July 5

A DISTINCT improvement in many of the lines of iron and steel has been noted during the week. The outstanding feature is the placing of a large order for rails and attachments by the Canadian Pacific Raliway. The demand for general lines has improved to such an extent that an upward revision in prices has been predicted. The railways are showing a tendency toward coming into the market to a greater extent than they have done heretofore this year. Supplies of various kinds are in demand. Pig iron sales are improving, with the sales of Scotch iron featuring the market. Machine tool conditions remain unchanged. The non-ferrous metals show a little more strength which is only about what was required to offset the weakness developed last week. The scrap metal market is quiet.

Iron and Steel.—A decidedly better tone prevails in all lines of the steel business locally. The pressure of orders for the smaller steel products and the occasional order for larger material, has caused the stiff quotations of last week to be revised upward. Base prices of iron and steel are now from $3.15 to $3.25 according to the size of the order. During the week the Canadian Pacific Railway has placed orders with the Algoma Steel Corporation for 48,000 tons of 100 lb. Type R. E. rails, together with the necessary tie plates and rail joints. This will keep the mills at the Sault occupied for about two months, operating one shift. Orders have been placed elsewhere for the spikes, bolts and other accessories.

The demand for black, blue annealed and galvanized sheets is still greater than the supply. The Montreal jobbers claim that they are unable to keep in stock any standard sizes and gauges of galvanized sheets. Prices on sheets are unchanged in spite of the above conditions. The demand comes from the building operations and the sheet metal working industries.

Stocks of structural steel are getting very low locally. Little of this material has been rolled in Canada for some time past. Poor deliveries from the United States mills have kept the business in Canada. This condition has resulted in depleting the local supplies. Up to the present no plans for rolling structural sections have been made. If the demand keeps up at the present rate it will not be long before steps will have to be taken to avert a shortage.

Merchant bars are moving fairly well, but the number of orders are not tending to embarrass dealers. The products mentioned above are much more active. Small steel products such as nuts, bolts, screws, etc., are moving very well indeed.

June has been the best month so far this year. With the exception of plates all products are moving well. Local quotations are as follows:—

Iron bars	3 15 to 3 25
Steel bars	3 15 to 3 25
Reinforcing bars	3 15 to 3 25
Steel hoops	4 00
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron.—Some large sales of Scotch Summerlee iron have been made during the week. Two local firms have each purchased five hundred ton lots, while one firm in Quebec placed an order for two hundred and fifty tons. This iron is being delivered on the docks at the St. St. Lawrence ports for $29.75 and to this amount must be added cartage and wharfage charges. The local quotation on No. 1 iron of the Canadian product is $31.80, which is the figure that has been asked for some weeks. The ocean freight on the Scotch iron is understood to be $3.40 from Glasgow. Rails rates from Central Ontario points exceed this figure, while from the Sault to Montreal the rate is about $6.50 per ton. Thus where all water shipment can be effected the Scotch iron can be obtained at a figure which averages about one dollar per ton less than the figure quoted on Canadian iron. In spite of the large sales of Scotch iron the sales of Canadian iron have also increased, particularly in the inland districts. Thus the condition of the market is greatly improved.

Machine Tools.—The machine tool market continues to be rather discouraging. The demand for some months past has been next to nothing. Only occasionally a sale is reported, and then it is usually for one small sized machine. In common with other parts of the country the demand for small screw machines for radio work has been the result of a few sales. There is a limited demand for used equipment of the better kind. A large number of sales in the past few months have been to garages. This class of prospect is also interested in the many developments of the portable tool. Present indications are that there will not be any great improvement in this market for some time yet. All business is keenly sought and the prices have been pared to the smallest margins.

Shop Supplies.—This business still continues to be very satisfactory. The demand comes from the small shops largely and is pretty well scattered over the country. Local contract shops are busier than the manufacturing shops, and thus they create the larger portion of the demand locally. No important price changes have been made during the week.

Non-Ferrous Metals.—The weakening tendency of the non-ferrous metal market that was present last week has been checked but the condition at this time could not be described as being strong. Local sales are about the same as last week and, with the exception of tin, no changes in quotations have been made. The quotations are as follows:—

Lake Copper	17 50
Electric Copper	17 25
Castings, Copper	17 00
Tin	34 50
Lead	6 75
Spelter	7 75
Antimony	6 50
Aluminum	23 00

Scrap Metals.—The scrap metal market remains unchanged. With the advance in prices of steel there is a tendency toward stiffening in certain lines but no change has been made in quotations. Local holdings are rather small in most cases. The foundries have come into the market for pig in the last week and it is expected that the demand for scrap iron will improve somewhat. The volume of business offering is about the same as last week.

Pittsburg

THE turnover in the steel market, in point of tonnage, has decreased farther in the past week, there having been indeed a more or less steady decrease for several weeks, the most active market having been in April. While the tonnage turnover is relatively light it would hardly be entirely accurate to describe the market as "quiet" for the reason that there is considerable pressure for early deliveries. The tonnage thus bought is not large, but the market is kept from appearing actually dull.

The mills say that the lighter turnover at present is due to their indisposition to sell, and assert that they could dispose of large tonnages if they were willing to accept the business offered them by customers. This, however, would be chiefly in the form of contracts for delivery late in the year, and the mills are no doubt just as well off without such business, as the buyers would specify freely if the market should prove strong late in the year, and otherwise would be indisposed to specify.

July and August are almost invariably very dull months in the steel market and this year will furnish no exception, as the stage has practically been reached already. This does not make the market any less strong, for the mills are well sold up through the two months, and in some lines, particularly in merchant bars, they are sold for a longer time. Whether all buyers are covered to an equal extent is a question, the present buying for prompt delivery indicating that they are not.

The market is quotable unchanged as follows: Bars, shapes and plates, 1.60c to 1.70c; hoops and bands, 2.40c to 2.50c; blue annealed sheets, 2.40c to 2.50c; black sheets, 3.15c to 3.30c; galvanized sheets, 4.15c to 4.30c; automobile sheets, 4.50c to 4.75c; tin plate, $4.75; merchant steel pipe, 71 per cent. basing discount; wire nails, $2.40 to $2.50. When a range is given the higher price is usually for early delivery.

Production and Prospects:—Now that the usual quiescent midsummer period is entered upon, the great question is how the market will shape itself up afterwards, say in September, when regular buying for the early Autumn should begin.

This question does not hinge to as great an extent as usual upon the prospects for consumption, relative to present consumption, for the reason that it is fairly well established that consumption is likely to continue increasing, at least for a time. Apart from the regular consumption of manufacturing consumers, there are freight cars and structural steel jobs, contracts for which have been made while most of the steel involved is still to be consumed. In the first half of the year about 92,000 freight cars were ordered, while only a small fraction of the number have actually been made.

The more important question hinges upon the relation between production and consumption in the past three or four months. It might be that buyers had gone too far, buying more steel than currently needed, but laying in stocks in fear of the coal strike making trouble. If consumption of late has been much under production, then a good sized increase in consumption might still make a tonnage less than the current production, which accordingly could not be maintained indefinitely.

While the question cannot be answered specifically, some figures bearing on it can now be cited. Production of steel ingots in the half year just ended has been about 16,000,000 gross tons, against 9,000,000 tons in the second half of last year and 10,000,000 tons in the first half. Production at present is at 39,000,000 tons or possibly even 40,000,000 tons a year. Can these figures be harmonized? There is an enormous increase in production, and it is plain that there has not been an equally enormous increase in consumption.

Stocks Liquidated in 1921:—Allowance must be made for stocks. Last year there was drastic liquidation of stocks, both of steel in the hands of buyers and of manufactured wares of various descriptions, including machinery, tools, hardware, agricultural implements, etc. The end of the year found the country quite bare of stocks, perhaps unprecedentedly bare. There was not enough material in the hands of manufacturing consumers and distributors for the convenient and economical transaction of business. Probably it would be conservative to guess that the liquidation in 1921 was equal to at least 3,000,000 tons of ingots, which would mean that consumption in 1921 represented fully 22,000,000 tons of ingots instead of the 19,000,000 tons produced. Again it would probably be conservative to estimate that replenishment of stocks in the first half of this year to an amount equal to 2,000,000 tons of ingots would not represent undue stocking and might not even represent a reasonable restoration of stocks. If so, the 16,000,000 tons production in the half year would mean consumption equivalent to 14,000,000 tons, which would compare with 22,000,000 tons last year, representing an increase of 27 per cent. in the rate of consumption. Anyone can believe that there has been an increase of this amount. If this line of argument be accepted, it follows that there are no undue stocks now, in other words no weakness in the fundamental situation in that respect.

Careful About Advancing Prices:—This, however, does not fully defend the market, for we have steel production now at 39,000,000 to 40,000,000 tons, representing a much greater tonnage than the average consumption of the past six months. Consumption has been increasing, but perhaps not enough. In other words, the steel situation has not thus far laid up any trouble for itself, but it may in the next few months. With reasonable confidence on the part of consumers, things would move along rather smoothly. In some quarters it is said that there is danger of a "buyers' panic" next Autumn, buyers becoming afraid of prices and proceeding to liquidate thoroughly again. The advice to sellers from these quarters is to be very careful about advancing prices and endeavor to hold the market at a level that cannot be criticized. In the past few weeks the Steel Corporation has been notably indisposed to make advances in its prices in cases where independents have paved the way by advancing their prices, and of late some of the independents could be observed adopting a policy of reserve, not trying to push prices up as far as they could be pushed just at the moment.

Here and there statements are made that the ending of the coal strike may bring a heavier demand for steel. The mills know better, the universal experience being that consumers buy when they are afraid steel will become scarce and do not buy when it looks as if they could get steel whenever they want it. It would be rash to conclude, moreover, that a settlement of the coal strike would increase the production of steel. At best it will take time to settle the coal strike and then more time will be required to get the mines actually operating, while finally if an attempt were made to ship much more coal the limit of capacity of the railroads would be reached.

Pig iron remains quiet, prices being quotable unchanged at $25 for Bessemer and basic and $24 for foundry, f.o.b. valley furnaces. Freight to Pittsburgh came down from $1.96 to $1.76 on July 1. The market has been remarkably inactive.

New Equipment for the Hamilton Technical School recently, included six 14-inch lathes, three of which were placed with the D. McKenzie Machinery Co., Guelph, and three with the Perfect Machine Co., Guelph.

News From the Industrial Field

64. **Hardware and tools.**—An East London firm request catalogues and prices from Canadian manufacturers of hardware and tools of all kinds.

Montreal.—Cook and Leitch have been given the general contract for the building of warehouse for Masson and Sons of Montreal. Cost will be about $24,000.

63. **Iron and steel.**—An East London firm just starting in business is prepared to consider agency arrangements for shippers in Canada of iron and steel, all kinds.

The general contract for the construction of a factory for the Dominion Wadding Co., on Vinet St., Montreal, has been awarded to B. M. Shaw, 151 Metcalfe St, Montreal.

The Preston Woodworking Machinery Co., Preston, Ont., have secured the contract for the woodworking equipment to be installed in the new technical school, Sarnia. The list includes five lathes, one grinder, band saw, buzz planes, variety saw, surfacer, and mortiser.

Owing to a rule existing at Ottawa that names of firms interested in Canadian goods cannot be divulged except through the Department of Trade and Commerce, we publish below only the key numbers. Those interested can write the Commercial Intelligence branch at Ottawa for further particulars.

A paper tape measure is being rolled into German bolts of cloth arriving at Montevideo, Uruguay. This innovation permits the salesman to tell at a glance the quantity of cloth remaining in the bolt, thus economizing time and labor and preserving the cloth in better condition than when unrolled and re-rolled as required in the usual method of measuring. The tape is about half an inch in width and is marked off in yards and meters.

There is a distinct and steady demand in Belgium for Canadian hand tools of a great variety of types, says A. S. Bleakney, trade commissioner at Brussels. If Canadian firms can lay these tools down at prices which will compete with the United States tools on the market, says Mr. Bleakney, they can undoubtedly do business. Certain Canadian tools, including saws, hoes, rakes and forks, are already on the market, a fact which should encourage other Canadian manufacturers of tools to endeavor to supply a share of the hand tool requirements of this country.

According to a report received from H. M. Trade Commissioner at Wellington, the demand for lorries, particularly petrol-driven, has been considerable since the war. The number of motor trucks in use is much larger than in prewar days, and there is no doubt that their use is capable of still greater increase. At present financial restrictions interfere with purchasing. An extended field for the sale of heavy lorries is opening up amongst the co-operative creameries as the roads improve, and even at present they are fairly important purchasers. The smaller vehicles are being increasingly used by shops and stores for delivery purposes.

74. **Wood pulp.**—A large and responsible English firm in Buenos Aires, at present importing mechanical and sulphite pulp from Scandinavia, desires to establish connections with Canadian mills in a position to supply these products in large quantities, and able to export direct to the Argentine. Correspondence with manufacturers only is desired, and full details of present prices, of capacity for export, terms of payment and proposed conditions of agency should be provided in first letter, together with samples of products. Quotations must be given c. i. f. Buenos Aires. First-class references will be given and required. Also interested in newsprint.

CORRECTION

In a news item appearing in June 22nd issue of Canadian Machinery, an error was made in reporting as members of the directorate of the Parker Motor Car Co., Montreal, Sir Wm. Price, Col. Scott, Frank W. Ross and Thos. Craig. These gentlemen are not directors nor are K. F. Dewar and James Vernon connected with the Company as the article intimated.

P. H. Falter, the new vice-president and treasurer of the Electric Furnace Construction Co., of Philadelphia, Pa., is a graduate of the engineering department of the University of Michigan, and until recently has been vice-president and general manager of the Canadian Electro Products Co., at Shawinigan Falls, Quebec, a subsidiary of the Shawinigan Water & Power Co. Prior to his connection with the Canadian Electro Products Co., he had been general manager of the Baltimore Electric Alloys Co., in the manufacture of ferro-silicon and other electric furnace alloys, and for 13 years with the Aluminum Co., of America, in various capacities, including design, construction and operation of a number of its plants. Mr. Falter was also general manager of the Shawinigan Electro Metals Co., Montreal, manufacturers of metallic magnesium, and he has also had considerable experience on hydro electric power plant work at Sault Ste. Marie and Shawinigan Falls, Canada.

OTTAWA

Carleton County Council has decided to go ahead with the erection of an addition to the Court House to cost around $50,000.

The municipality of Eastview, Ont., requests tenders for the supply of hydrants, cast iron pipe, brass work, pig lead, special pipe casting and service posts up to noon July 10.

The Vimy Realty Co., of Ottawa, has awarded a contract to the Gilmour Construction Co. for a two-storey addition to their premises, 370-374 Sparks Street, Ottawa, to cost $30,000. The present building has been used for garage purposes. The new addition will be used for offices.

Plans for the new Bible House to be erected on Lisgar Street, Ottawa, have been accepted. The building will have a frontage of 22 feet and a depth of 40 feet and will cost $25,000. Work will be put in hand as soon as tenders have been called and the contract awarded. It is hoped to have the building ready for occupation by November 1.

General tenders are asked for the excavation, masonry brick work, reinforced concrete work, hollow tile, structural steel, stone work, carpentry, joiner work, steel casement ornamental iron, painting and glazing, roofing and sheet metal work, electrical conduit and wiring, plumbing, heating and ventilating of the new Collegiate Institute and Vocational school at Renfrew, Ont. Tenders must be in the hands of the chairman of the Board of Education, Renfrew, by 3 p.m., July 18.

A company known as Salvors Ltd. has been formed by Ottawa men to undertake marine salvage work, especially the raising of sunken merchant vessels, by an entirely new method, the invention of Capt. A. G. Midford, of Ottawa. The new method calls for the use of caissons, one for each 250 tons displacement of the vessel to be raised, which are placed on either side of the work with connecting chains that pass under the vessel. Air is then pumped into the caissons while a tug tows the vessel as it is raised, in order to keep it on even keel, until it is awash.

At a meeting of shareholders of Red Arrow Tires, Limited, June 28, it was decided to make an assignment. It was pointed out at the meeting that the only known assets of the company are a partly completed plant, some office fixtures and whatever money belonging to the company may be held by the stock underwriters.

It is expected that nearly $90,000 will be spent by the Hydro-Electric Commission in acquiring new rolling stock for the Guelph street railway.

The Campbell Steel and Iron Works will be awarded the contract for lighting posts on Cummings Bridge, this city, both the city and county having approved this firm's tender.

Anything can be sold in China by personal representation and display of samples, declares a recent trade report. There is a certain demand for large and small engines and electrical equipment of all kinds.

James W. Watson, of the Kitchener Pattern Works, and Albert Wendling, formerly foundry foreman of the Forwell Foundry Co., Kitchener, have launched the Aluminum Last and Metal Company. They will make shoe lasts of aluminum and do general jobbing.

Messrs. Richards and Abra, architects, of Ottawa, have submitted revised plans to the Carleton Place school board for the new high school to be erected there. These call for the erection of a structure, fire proof, to cost in the neighborhood of $90,000. Following acceptance by the board the plans will be sent to Toronto for approval of the provincial Board of Education. As soon as this is given tenders will be called for and it is expected the building work will be put in hand at the earliest possible moment.

Business generally is beginning to feel the effect of the good crop prospects. Lines such as dry goods and groceries are said to be moving better, and merchants state that they find a much better spirit prevailing among the retailers throughout the province. Firmer price tendencies in several lines of cotton and woollen goods, moreover, have tended to stimulate sales of these lines, while the advances recently noted in teas and sugar have caused better buying at the grocery houses. The active building program which is now in progress, moreover, together with railroad and highway work, are giving more employment to the workers, which means more money in circulation and a larger buying power on the part of the general public. Altogether, the outlook appears to be considerably more favorable.

The E. S. Bryant Pattern Works, Windsor, Ont., is a branch of the company of the same name in Detroit, Mich. The Canadian branch was established eighteen months ago, and from the very start have grown until they are now handling a considerable amount of automotive work. They are familiar with all classes of machine molding for production, also match plate work. Patterns that enter into the manufacture of automobiles are made, covering everything, where patterns for castings are required, from cylinder and other large patterns for machine molding, to the smaller patterns which are usually made up in aluminum match plates of several patterns of the same part for snap flask molding. The value of plant equipment is $17,000 and there is a total floor space of 6,000 sq. ft.

Fort William, Ont.—Col. Thomas Gibson, president of the Fort William Paper Co., who are operating night and day a 120 ton capacity pulp mill at the Mission, announces that plans have been prepared for the erection in connection with the pulp mill, of a paper mill with a minimum capacity of 100 tons of newsprint daily. Colonel Gibson stated that material would be assembled for the new industry immediately and they expected to have it in operation by August, 1923. The construction will mean an expenditure of over one million dollars, and the completion and operation of the mill will add approximately one hundred and twenty-five permanent employees to the Fort William company payroll. "We have also in mind plans for the extension of both our ground wood mill and the paper mill," added Colonel Gibson, "and if we have the support of the people of this district, it is our intention to make the Fort William plant a second Spanish River. More than that it is needless to say." The Fort William city council have ratified an agreement with the company meeting their wishes in connection with the proposed new mill.

BELIEVES BIG MARKET EXISTS IN WEST INDIES

"AN IMMENSE market for Canadian goods lies in the West Indies." This was the predominant thought expressed the other day at the C. M. A. convention held at St. Andrews-by-the-sea. Several speakers expressed their opinions, and here are a few excerpts from their statements.

"Canada is the logical supply source of the West Indies in preference to other countries," said Geddes Grant, Trinidad, because there is a subsidized steamship line between the two. Canadian banks are established there and have the highest reputation, and most of the islands have established preferential tariffs with the Dominion. With a population of 2,500,000. West Indies' imports totalled $24,000,000 per year." Mr. Grant emphasized the value of courtesy when buyer and purchaser were so far apart, particularly advising immediate acknowledgment of inquiries or orders.

W. H. Shapley mentioned that if Canada did not pay more attention to the West Indies they would be lost altogether. He remarked that Canada must buy more from the West Indies if the islands were to take Canadian products. Canada now consumed 2 259,000 bunches of bananas a year, but most of these while of West Indian growth, were brought through the United States. Oranges valued at $9,000,000 were bought each year, chiefly from California, to the neglect of the West Indies growth. The bananas alone, if imported directly into Canada, would give 7,000 carloads of traffic to the country's railroads.

BETTER BUYING IN WEST CONDITIONS FAVORABLE

OPTIMISM throughout the West as the result of very encouraging crop prospects is reported by A. S. Capwell, manager Buffalo Forge Co., Kitchener, who has just returned from a trip to the coast. In Winnipeg there is considerable building going on, and at Edmonton, Calgary, and Vancouver there is similar improvement in this industry. On the outward trip the outlook in some sections was not the best, owing to lack of rain, but on returning eastward he found that two or three days' downpour had improved the general spirit.

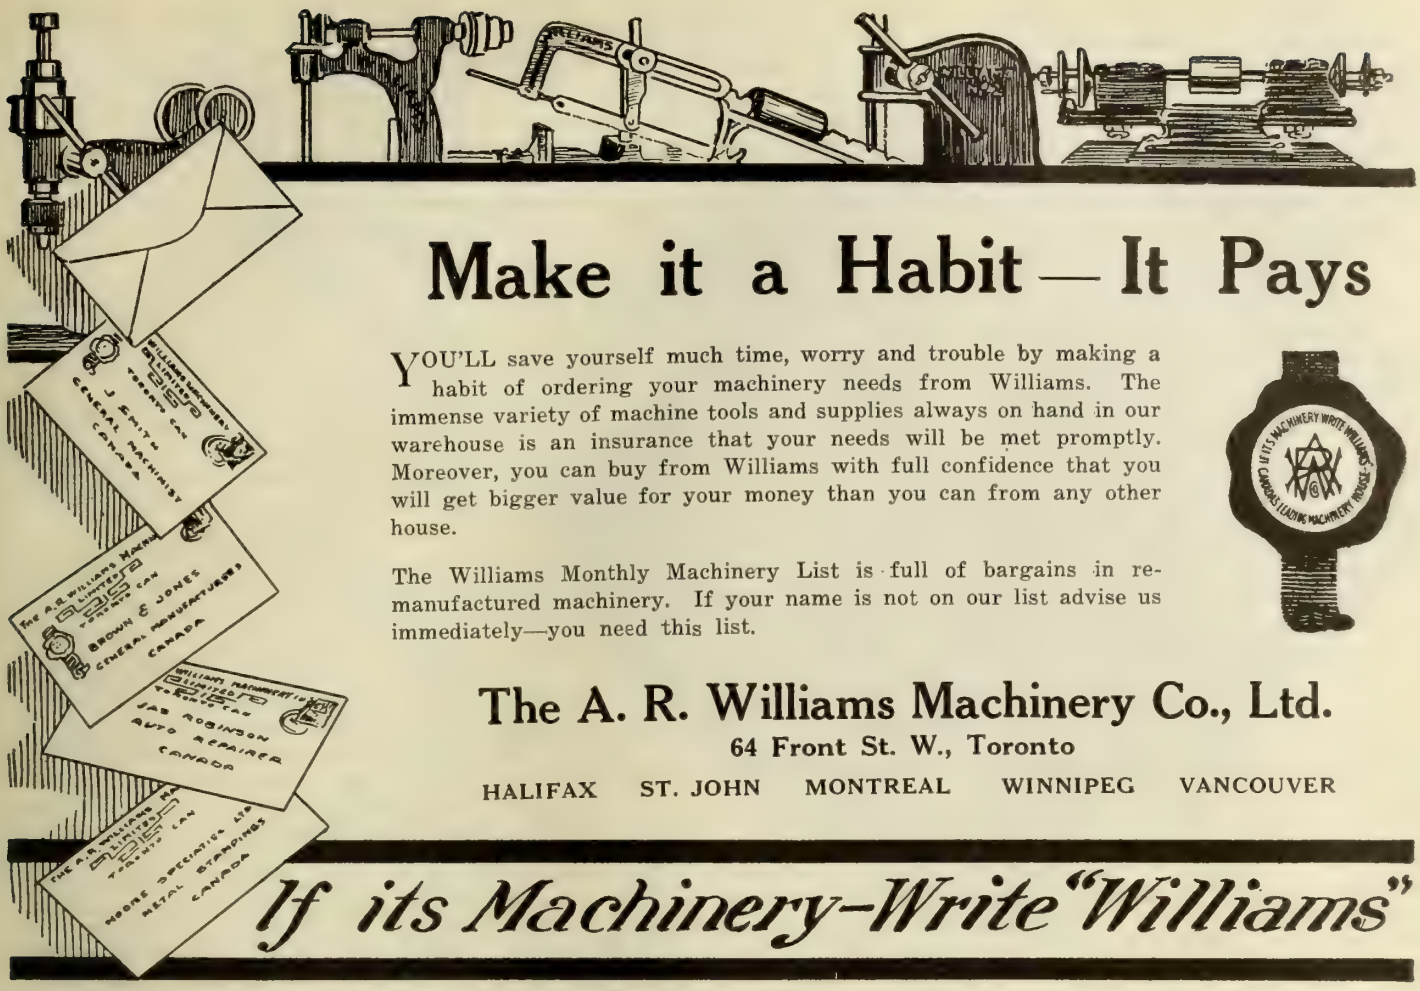
As an instance of the buoyancy caused by a timely rain, Mr. Capwell states that he was able to close business on the return trip which had looked doubtful two weeks before. The rain seemed a blessing to business generally, as well as a boost to crop prospects. At the present time, it appears, the West will bank on favorable weather, and buying improves accordingly.

At Trail, B. C., and also at Britannia, B. C., the copper mines are installing much new equipment. The lumber industry on the coast appears to be developing a boom. The domestic and export demand has improved, and a recent advance of $4 a thousand is reported. A thriving condition in the prairie provinces, brought about by bumper crops, will be welcomed by the B. C. lumber industry. It means the re-opening of a market that has been indifferent for some time.

On his return from the West Mr., Capwell was called to the general sales conference held at the head office of his company in Buffalo. Here the entire sales staff of the Buffalo Forge Co., Buffalo Steam Pump Co., and the Squier Co., the latter manufacturers of sugar-working machinery, was assembled, thoroughly representing United States fields, and it is significant that all reports pointed to greatly improved conditions.

SUBMARINE ENGINES FOR ELECTRIC POWER STATIONS

War, it is a comfort to reflect, has its uses for times of peace, especially when it involves the capture of valuable engineering plant. When Germany surrendered its submarines, six of the engines thus provided were installed in a British electric power station, the total cost being about half the ruling cost of ordinary engines of a similar capacity. The engines were thoroughly overhauled and reconditioned by a British engineering firm before being put into action again; and as they were oil-driven they proved of great value during the coal strike last year. They have also proved much more economical than the steam-driven sets which previously did the work in that station.



Make it a Habit — It Pays

YOU'LL save yourself much time, worry and trouble by making a habit of ordering your machinery needs from Williams. The immense variety of machine tools and supplies always on hand in our warehouse is an insurance that your needs will be met promptly. Moreover, you can buy from Williams with full confidence that you will get bigger value for your money than you can from any other house.

The Williams Monthly Machinery List is full of bargains in re-manufactured machinery. If your name is not on our list advise us immediately—you need this list.

YEATES MACHINERY

HALE STREET
LONDON, ONT.

Brig. Gen. T. L. Tremblay, C. M. G., D. S. O., has been appointed general manager and chief engineer of the Quebec Harbor Commission, and will continue to perform his duties as Harbor Commissioner.

The extension now being constructed to the factory of the Steel Trough and Machine Co., at Tweed, Ont., will give an additional 5,000 sq. ft. of floor space. This firm specializes in the manufacture of heavy sheet metal products.

The Volta Mfg. Co. of Welland, Ont., has just received an order for a standard three-ton capacity electric steel furnace, with transformer and switchboard equipment complete, from Renton & Fisher of the Hopetown Steel Works, Bathgate, Scotland.

Several changes among the C.P.R. officials are announced. Alfred Price after 40 years service latterly as general manager of Eastern lines, is succeeded by John F. Scully. Geo. Hodge, assistant to Vice-President McTier, becomes assistant general manager Eastern lines.

Contracts for machine tools for Sarnia Technical School have received departmental approval. An order has been placed with Canadian Fairbanks Morse for one milling machine, one shaper and one tool and cutter grinder. The Chas. A. Strelinger Co., Windsor, received an order for lathes, and heat treating furnaces. The woodworking machinery was placed with Preston Woodworking Machinery Co., Preston, Ont.

The Herbert Morris Crane and Hoist Co., Niagara Falls, Ont., announce in connection with their organization in United States (Herbert Morris, Inc.) the opening of offices and warehouses in Boston, New York, Chicago, Detroit and Buffalo. In the latter city a manufacturing plant has been established. The company's representatives in these cities are: Boston, R. Gillespie; New York, D. E. Hamilton; Chicago, A. C. Perrin; Detroit, J. B. Candlish; Buffalo, W. C. Kuebrick.

While being hoisted into a second story window, a heavy iron lathe fell to the pavement, 25 feet below. The six men of the cartage crew, having the job in hand, had a narrow escape. In hoisting the machine they had rigged a block and tackle attaching one end of the rope to the lathe and the other to a truck, which was hauling the lathe into the air, when a delivery car drove into the rope and snapped it. The men jumped aside. The driver of the delivery car, who failed to see the rope, declares that it was unguarded, and it is stated that the charge of obstructing traffic will be preferred against the cartage company for obstructing traffic.

Employment service officials state that, recently, some very fine young men have come out from England under the auspices of an organization known as the Church Army. These youths have had some agricultural training, the system embodying three months with horses, three with cattle, three in dairying and three in carpentry. It is told of one of these youths, who sported spats, a cane, a stiff hat and other evidences of superiority, that, on being asked if he could milk cows, replied with some traces of timidity. "Well, I have milked an English cow, but I may not know your Canadian animal." The farmer who was negotiating the matter pointed out that the Canadian cow had nothing on the English breed, and a deal was closed. These boys are picked up rapidly at a wage of about $18 monthly.

John McPherson Taylor, eldest son of John M. Taylor, president and general manager of the Taylor-Forbes Co., Guelph, died June 30, after a brief illness Mr. Taylor was born in Toronto in 1889. At the time of his death he was assistant to the general manager of the Taylor-Forbes Co. He is survived by is wife, four sons, two sisters and two brothers.

Building permits issued during the first half of 1922, ending June 30 in Ottawa totalled $2,385,241 as compared with $1,165,570 in the corresponding period of 1921, or an increase of $1,219,671. For the month of June alone the amount of new construction authorized was $421,600 and the number of permits issued 101 compared with 70 permits with a valuation of $163,585 in June 1921.

EXPANDING THE MARKET FOR RAW MATERIAL

(Continued from page 64)

economies of construction, more highly fire resistive construction, consequent reduction of national fire losses—a distinct service to the public, an establishment of a certain amount of resultant good will, and an extension of the market for cement.

We distributed several million educational-informational booklets last year. These discussed the advantages of the use of cement in the form of concrete construction in many fields. Concrete on the Dairy Farm, and around the home, are typical titles and we have a series of booklets devoted strictly to concrete construction in specialized structural fields. These are continually revised by incorporation of the latest information disclosed by study, research or experience and are in that way kept up to date.

We use miles of motion picture films. We have a film showing the numerous processes involved in the manufacture of portland cement. It does not require a high order of intelligence after having seen this film to realize a sack of cement represents the combined expense or cost of many operations, one of which, for example, is the use of 50 pounds of coal.

The advantages of paved barnyards are displayed through the medium of animated cartoon films circulated in rural communities. We have many reports showing that after a local cement dealer had displayed one of our animated cartoon films in his community, he sold within a week or ten days cement for several concrete feeding floors. Of course, we have no connection with cement dealers other than placing at their disposal motion picture films or other educational matter which they may wish to use in the immediate furtherance of cement sales. Occupying this unique position with relation to the industry, we can devote our whole time and such talent as we have to further expansion or extension of our educational methods and to the development of new ones.

BOOK REVIEW

The June issue of The Empire Mail is a special number commemorative of Empire Day, and contains a remarkable series of messages from eminent men in many spheres of Imperial thought and activity. The Marquess Curzon, Foreign Secretary, writing on the present depressing symptoms, says these will not endure, and calls upon the Commonwealth of free British nations to solve its own problems and thus set an example for other countries.

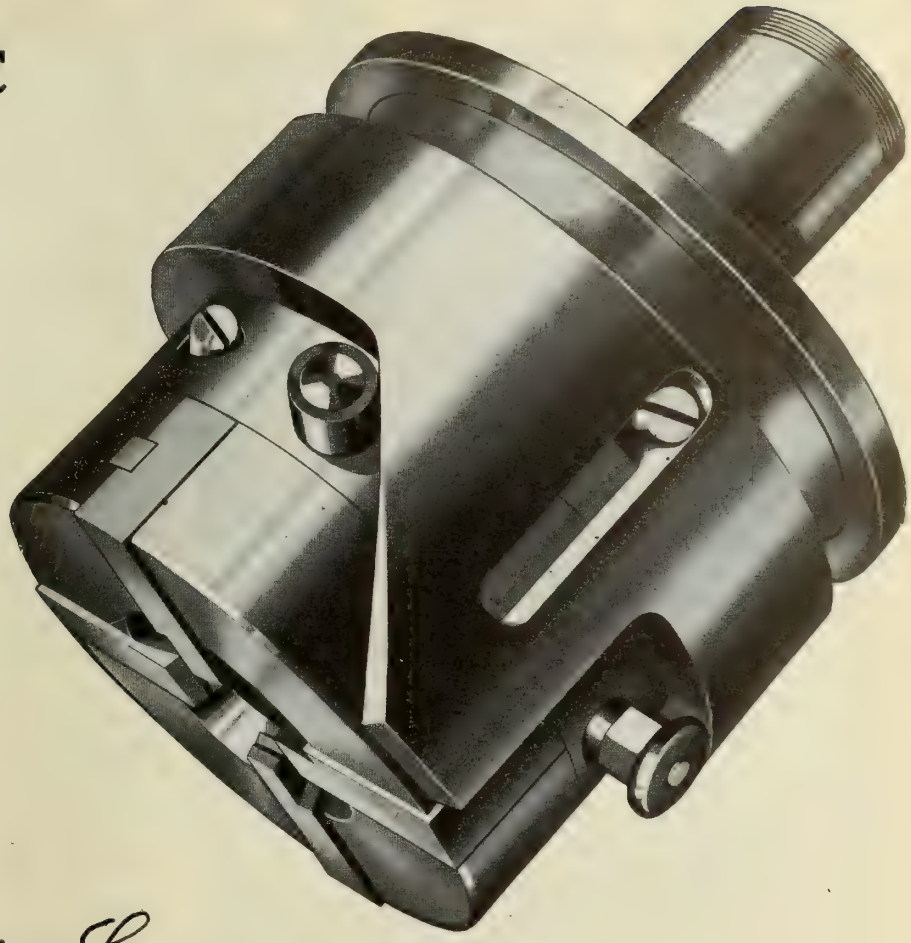
Mr. Winston Churchill, Colonial Secretary, urges firmness, coolness and patience upon all loyal and faithful subjects of the King. Other contributors to the Number include Lord Lee, First Lord of the Admiralty; Mr. Edward Shortt, Home Secretary; Sir Hamar Greenwood, Chief Secretary for Ireland: Sir A. Griffith-Boscawen, Minister of Agriculture; Mr. F. G. Kellaway, Postmaster-General; Lieut.-Col. Amery, M. P.; Lord Burnham; Sir Eric Geddes; Mr. Walter Runciman; Field Marshall Sir Henry Wilson, M. P.; General Bramwell Booth, and many others. Taken in all, it is a splendid issue and well worthy of notice. We have not space to comment on even a small percentage of the features.

MACHINE TOOL MERGER

It is stated that negotiations have been completed for the amalgamation of a number of machine tool firms having an aggregate capitalization of $30,000,000. The new enterprise will be known as The Consolidated Machine Tool Corp. of America. Among the firms mentioned in the report are the Betts Machine Co. of Rochester; Colburn Machine Tool Co., of Rochester; Colburn and Jones Co., of Wilmington; the Modern Tool Co. of Erie; and the Newton Machine Tool Works of Philadelphia. The offices of the new corporation are at 17 East Forty-second St., New York.

The Hunter Bridge and Boiler Co., of Kincardine, Ont., has been awarded the contract for the steel work in connection with the new bridge over the Sangeen River in Brant Township.

GEOMETRIC ROTARY DIE-HEAD



Right in the Lead

One of the Die Heads that has put production on the increase and costs on the decrease.

This Rotary Die Head, which made itself famous on the Geometric Threading Machines, is adaptable for rotating on other types of machines, such as Drill Presses, Bolt Cutters, etc.

Let us know the machine on which you desire to use the Geometric Rotary Die Head, and a suitable shank will be applied.

To Get Quick Production of Screw Threads Without Waste, Try a Geometric. They are sent on trial to Reliable Concerns.

Expanding The Market For Raw Materials

Each Branch of Industry Is Related More or Less to the Other, and a Cessation of Activity in One Is Sure to React on the Others —Educational Methods Have Brought Results

By H. COLIN CAMPBELL

PROBABLY no one will ever complete a list of all ways and means to expand markets for raw materials. Certainly a dominating method is to know as much as seems possible about the adaptability of such materials. This known, it is evident that one can then direct his attention toward seeing that they are used so that the best results possible will be realized. The ways of using any given raw materials may be numerous. Steel intended for horseshoes does not pass through the same processes as steel converted into watch springs.

Many people if asked to give the dictionary definition of raw materials might be unable to do so. They would, however, be able to make clear their understanding of the term by mentioning wool, cotton, iron, clay, and a great variety of other materials which in their basic form are of little or no use to mankind. These materials acquire real value to mankind only after having been put through one or several manufacturing processes which convert them into what is commonly called finished products.

To the man who needs a suit of clothes, its equivalent weight of unspun wool or unwoven yarn is worthless. The man who needs mortar to lay cut stone, brick, or concrete sees nothing that will satisfy his need in the mountain of rock, which after being put through a multiplicity of processes becomes portland cement. Yet the mountain of rock has a distinct value because a market has been made for it through the discovery that when put through certain processes it will become one of the strongest binding or bonding materials known.

However, portland cement even after having reached the dignity of a manufactured product is still a raw material until those who are to use it know and supply the way and means necessary to most efficient and effective use. Likewise, a suit of clothes remains raw materials so far as the individual purchaser is concerned if it is so small that he cannot get into it or due to any other fault he cannot obtain in satisfaction or service the equivalent of its price.

I believe the unqualified statement may be made that no manufacturing concern and no producer of any raw material, as first defined, can separate or isolate himslf from the many and varied enterprises going on about him if he expects success. A careful study will disclose a lead which shows his relation to, and interdependence upon many other enterprises, seemingly remote from his commonplace individual interests, and of vital concern to the ultimate and continued success of his business.

If I happen to refer frequently to, or dwell at some length upon the manner in which the Portland Cement Association endeavors to expand the logical market for cement, I hope you will accept as the reason the fact that in our methods are found as striking examples as can be to illustrate ways and means of expanding markets.

Inter-Relation of Operations

The discovery that a mountain of raw materials could be converted into a product known as portland cement is in itself an illustration of the expansion of markets. There are not far from 100 distinct operations that must be performed before a sack of cement can be turned over to a prospective purchaser as a product ready for use. Each one of these operations requires some related operation, manipulation, or process, the use of some device, the carrying out of some method that calls for machinery, fuel to drive it, laboratory work of a high order to determine quality. In other words, the seemingly simple process of tearing down a mountain and putting it through a sieve makes, sustains, and expands markets for a variety of other raw materials in direct ratio to the demand developed for the finished product.

If cement mills were to be shut down because there were no longer any demand for their output, there would immediately follow a reduced market for iron and steel, a great variety of tools, machines, dynamite, and other things necessary to equip and operate such plants. As a result there would naturally follow the loss of a field for the sales efforts formerly directed toward securing purchasers for the product normal to the abandoned industry. In other words, the far reaching effect of continuance or suspension of cement manufacture would soon become evident.

The development of the automotive industry has caused a great deal of latent talent and inventive genius to become productive, which has created wealth by expanding established markets not only for well known materials but has created markets for new ones. An automobile requires grades of steel and other products that were unknown or not in special demand before the motor vehicle became established. Inventive and research genius were directed toward making the discoveries that would produce the necessary steel with the required chemical and physical properties. As a result raw or basic materials that before had never entered into commerce found a market had been established for them.

A luxurious car requires special upholstery, many trappings and trimmings that add to utility as well as convenience. All of these are regarded as necessities to the car owner and for that reason are recognized articles of commerce. The demand for them, created by taste, pride, avarice or what not, has been reflected in new demands on the textile, steel, and related industries which you can readily enumerate for yourself.

The Portland Cement Association is purely a voluntary organization. In popular conception, it is classed with other organizations referred to as "trade associations." While there are other associations operating as we do, I think it safe to say that our method of operation is unique in that it has greater ramifications than any other organization with which we may be compared.

Practically all of the cement manufacturers in the United States and Canada belong to the Portland Cement Association. We have members even in Cuba, Mexico, and South America. The fact that we have these foreign members may seem strange to you when I tell you that the association is not in any way concerned in the commercial aspects of the cement industry. The reason for this foreign membership is undoubtedly due to the far reaching effect of our educational work and the inestimable value which cement manufacturers place upon it as an aid to stabilizing and expanding the market for their product.

We have twenty-four offices conveniently located in different parts of the country. The underlying idea of the association is expressed in that often used, much abused and sometimes meaningless word "service." Our headquarters in Chicago are the executive center for all of the activities in which we engage. Each district office is a service organization like our headquarters office but on a smaller scale, although sufficiently comprehensive to quickly and efficiently serve the territory of which it is local headquarters. Depending upon the number and intensity of various campaigns we may be engaged in, our staff averages around 300. Most of our men are technically trained—usually civil engineers. Also most of them are, or soon become peculiar engineers

---

Author is manager of advertising and publications bureau Portland Cement Association, Chicago, and this material is a portion of some facts he presented before the First National Industrial Advertising Conference at Milwaukee, Wis.

ATKINS
METAL CUTTING SAWS

Solve your Metal Cutting problems, easily, quickly and economically, by adopting the products made by

ATKINS

We make Kwik-Kut Power Hack Saw Machines which use practically the full cutting edge of the Hack Saw Blade at each stroke; Metal Cutting Band Saw Machines for general shop work, cutting all classes of metal up to 12 x 14 inches.

Your requirements for Metal Cutting Circular Saws can be supplied promptly and we solicit a trial of our "AAA" Non-Breakable and Power Hack Saw Blades and Frames.

"A Better Saw for Every Use"

E. C. Atkins & Co.

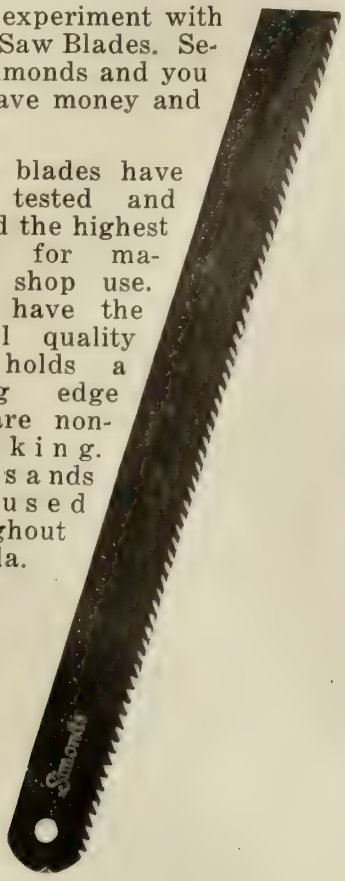
"The Sterling Quality Saw People"

Factory: HAMILTON, ONT. *Branch:* VANCOUVER, B. C.

SIMONDS
Hack Saws

Don't experiment with Hack Saw Blades. Select Simonds and you will save money and time.

These blades have been tested and proved the highest grade for machine shop use. They have the steel quality that holds a cutting edge and are non-breaking. Thousands are used throughout Canada.



Simonds

in that they are able to keep their technical or professional training from interfering with the ability to put their ideas and aid in such form as to make popular consumption easy. They are trained in promotion. They are salesmen who have nothing to sell but an idea, which is "Concrete for Permanence."

Our headquarters, as well as various district offices are departmentized. Specialists are delegated to various classes are best suited. Agriculture, building construction in its broadest sense, sanitation, highway engineering, from the simplest to the most stupendous structures required in any given field, are all reduced to terms of concrete.

Probably the backbone of our whole educational scheme is in our structural materials research laboratory, operated jointly and in co-operation with the Lewis Institute, Chicago. Here a large corps of practically trained technical men are engaging in research work on the various uses of cement and concrete. Since 1916 considerably more than 100 000 chemical and physical tests have been made in this laboratory solely to determine how best to use concrete, as well as how not to use it—in other words, discovering and establishing the possibilities of cement as expressed in concrete construction.

Learning All the Time

In spite of the fact that the Association is twenty years old, and during all that time has been attempting to further knowledge on the use of concrete, it may startle you to know that within the last seven or eight years we have learned more about how, and how not to use it than was known in all the years before.

The evident advantages of concrete construction were early recognized and tempted many to write their own specifications, so to speak, for using the material, with the natural result that cement—the principal ingredient—was discredited because of faulty use. It was evident, therefore, that practical guidance, based on scientific knowledge and established facts, was necessary to prevent abuse of a worthy material.

Until within comparatively recent times, nothing was known as to the effect which clay and other impurities as an admixture with the sand and pebbles used in concrete might have on the strength of a finished structure. Studies have been made in our laboratory on the effect, size and grading that aggregates have on concrete, the effect of using different types of aggregates, the effect of various impurities in aggregates, the effect of various powdered admixtures in portland cement such as coloring matter and hydrated lime used for a definite purpose, the effect of impure mixing water such as impurities caused by industrial waste, etc.

At first glance these studies might seem as having but remote connection to expansion of the market for cement.. However, as an example, our studies on the effect of size and grading of aggregates as related to a concrete mixture have been most forcibly illustrated on a piece of concrete highway construction now in process in the Imperial Valley, California. At the quarry where aggregates were being obtained for the concrete used in this pavement, methods employed in screening the crushed stone for the concrete mixture caused a waste of 35 per cent of the materials taken from the quarry. One of our field engineers, who was interested in watching the progress of this work and was rendering the usual co-operative service to those in charge, suggested that a change in the methods of screening materials, based on our laboratory tests, would considerably reduce this waste of materials. His suggestion was adopted with the result that a waste of only 15 per cent. followed changed methods in screening. Instead of costing $1 a ton to prepare, the stone then cost 42 cents, or expressed in dollars, $30,000 were saved, which made it possible for the community concerned to build an extra mile of concrete road. This of course is not the only example of its kind. It is, however, the most recent one of such magnitude.

Among the various classes of educational work that we carry on are lectures before agricultural colleges, farmers' institutes, engineering colleges and universities, co-operation with county agents, architects, engineers, contractors, building commissioners, having to do with revision or writing of building codes, vocational schools in which we endeavor to establish simple courses in manual training through the use of concrete, etc. You will also find our field engineers on many a piece of concrete construction serving in an advisory, consulting or inspecting capacity in co-operation with the engineers, contractor or architect under whose immediate supervision the project is going on. We also have a motor truck with complete concreting equipment and gang giving demonstrations in the actual "how," travelling throughout various parts of the country.

A rather amusing controversy took place not long ago among our district engineers. The question was being argued just how far the functions of an association fieldman should go in rendering the service for which the Portland Cement Association stands. It finally sifted down to an agreement that if there was a job going anywhere these days and one of our men was found on the job without concrete on his shoes, he was certainly not running true to form.

We have assisted a great many aspiring men to go into the contracting field, specializing in concrete construction. We have promoted through educational work a higher standard for building codes in many cities and are continuing this work everywhere that our aid is asked. The result of this is certain to be expressed ultimately in

(Continued on page 60)

Making Fine Tools

An Interesting Operation, Economically Performed by Means of a DUMORE Grinder

This photograph — taken at the City Engineering Company's (Dayton, Ohio) plant shows a Dumore Grinder finishing the main shank and head of a special draw-in collet. There were 500 put through in this special lot and the time for the operation shown averaged 8 minutes per piece.

The second operation; grinding the internal face of the collet nut, was also performed by this convenient precision tool.

Dumore Grinders are popular here as in every plant where fine tools are made. Their accuracy makes them useful for the finest finishing work; their simplicity and convenience make them practical for many difficult, almost inaccessible jobs.

Dumore Grinders transform any lathe into a precision grinder; they make fine finishing possible in every machine shop.

May we tell you more about them?

Effective Co-operation

THE three newspapers you see illustrated here belong to the MacLean Technical Group.

If you are a manufacturer of equipment that can be used in machine shops, metalworking plants, power plants, or foundries, one or all of these papers can give you effective cooperation in increasing sales.

Tell the consumer about your products in the columns of these publications. The men who buy industrial equipment read them. Your products may have advantages over other products of their kind.

Tell the consumer what they are. Create a desire in his mind to buy your lines when ordering from the dealer.

An effective message in MacLean Technical Newspapers will prove effective cooperation for the promotion of sales, and the group you can use to greatest advantage includes:

CANADIAN MACHINERY
AND MANUFACTURING NEWS

POWER HOUSE

CANADIAN FOUNDRYMAN
AND METAL INDUSTRY NEWS

Canadian Machinery serves the iron and steel and general metal working industries.

Power House serves steam, electrical, water and gas power plants.

Canadian Foundryman serves the grey iron, steel and non-ferrous foundries.

Each of these papers covers their respective fields almost exclusively. They are "Canadian National" in scope and are read by the men you are anxious to reach—proprietors, managers, superintendents, purchasing agents and foremen. Attract the attention of these men with a strong appeal in their favorite technical newspaper—the MacLean service staff will assist you.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

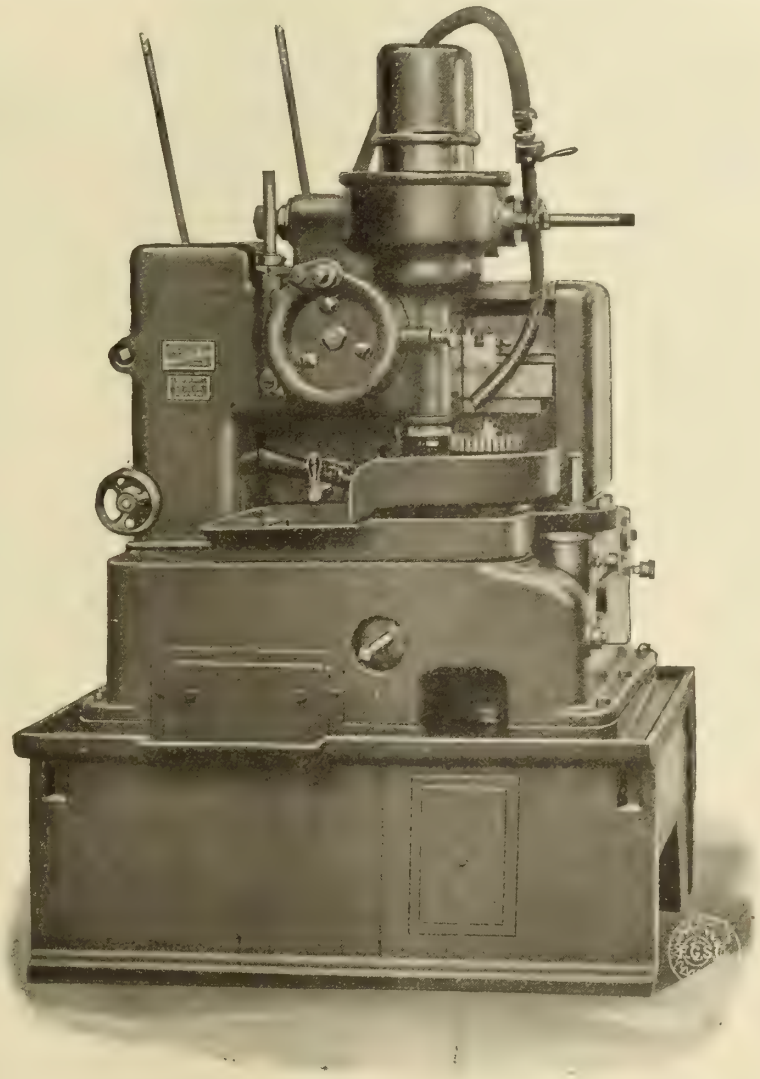
CUT GEAR COSTS
WITH THE
New Production Gear Shaper



The new production Gear Shaper, illustrated, has been designed to cut gear costs. It incorporates every feature necessary in a gear cutting machine to obtain this result, and still one of the outstanding features of the Gear Shaper principle—accuracy—has been maintained.

It is designed to cut one gear at a time and at a speed which eclipses all other methods.

All operating levers are at the front of the machine, permitting a number to be bolted together and operated as a unit, one 6 H.P. motor furnishing ample power for 10 machines

It incorporates to the fullest extent the three principal requirements of production—high speed, accuracy and simplicity of operation.

See illustrated article in all technical magazines.

Send for our booklet, "A New Development in Gear Cutting," which has been prepared for the benefit of Engineers and Production Managers interested in the best gear cutting equipment available.

Write for your copy now.

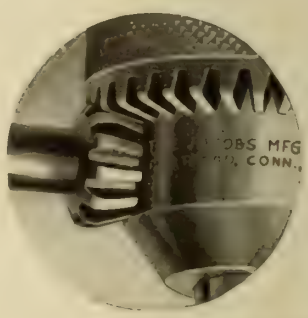
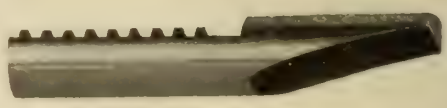
Jacobs Super Chuck

Patented 1909-1915. Other patents pending

A Look Inside

Here are the several parts—carefully designed, exactly fitted, perfectly made—that guarantee the Jacobs Super Chuck to hold a drill tight, to hold it right, and to keep on doing its work indefinitely.





FIRST THE BODY—scientifically casehardened; size limits within .0005″, arbor hole ground on a special fixture with six gauges to position it accurately in relation to the hole for the jaw.

THE SLOT FOR THE NUT, correctly located in relation to the jaw holes by means of micrometer gauges, insures a properly fitting thread on the nut and jaws.

NO WEAR ON KEY HOLES because of the deeply casehardened body, result—a well-fitting Gear on Sleeve and Key.

THE JAW, OF TOOL STEEL, has glass hard gripping surface; threads are tough, and all surfaces are ground on centers to within **a quarter of a thousandth** of an inch.

THE NUT, of special analysis steel, is ground after heat-treatment, in correct alignment with thread, tolerance .0005″.

THE BALL RACE comes within limits of .0001″; finest grade balls are used. An important point is the pitch of thread on nut—angle is 90 degrees to center line of jaw, so part cannot run over thread of latter.

The Jacobs Super Chuck centers a drill, **accurately**, and will continue to do so after years of use. It saves its cost time and again by preventing drill breakage. Its correct balance preserves bearings of your drilling machine—order a Super Chuck from your dealer.

ATKINS METAL CUTTING SAWS

Atkins Latest Improved Metal Band Saw Machine

(PATENTED

Atkins Metal Cutting Band Saw Machine

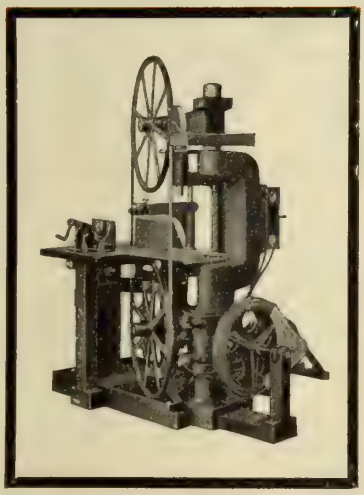
This illustrates ATKINS No. 3 Metal Band Saw Machine—fast, accurate and economical. It is the last word in metal cutting machines.

Large Capacity

For general machine shop use; cuts all kinds of steel, iron and metal up to 12 inches by 14 inches easily, quickly.

Important Features

The machine is provided with Automatic Tension Gauge which indicates the correct tension for the blade. This is a saw saver. Other features are Quick Acting Vise, adjustable to any angle up to 45 degrees. It also has Vertical Cut which is an assurance that the blade will travel in a straight plane; Automatic Stop to stop the saw the second cut is completed; Gravity Feed; Hinged Table, and Adjustable Saw Guides.



A Machine That Pays Its Way

If you want to save money and speed up production, get the complete specifications of this machine. Install one at the first opportunity.

Upkeep Expense Is Light

Hyatt Roller Bearings are used in the bearings which is a guarantee of long life for the machine as well as accurate and smooth cutting.

In Canada

You can obtain prices and complete specifications of Atkins No. 3 Metal Band Saw Machine by addressing our Canadian Works, E. C. Atkins & Co., Hamilton, Ont. Inquiries and orders given immediate attention.

Other Products

We manufacture Circular Metal Cutting Saws, Hack Saw Blades, Frames; Hack Saw Machines, Hand and Cross Cut Saws; Machine Knives, etc.

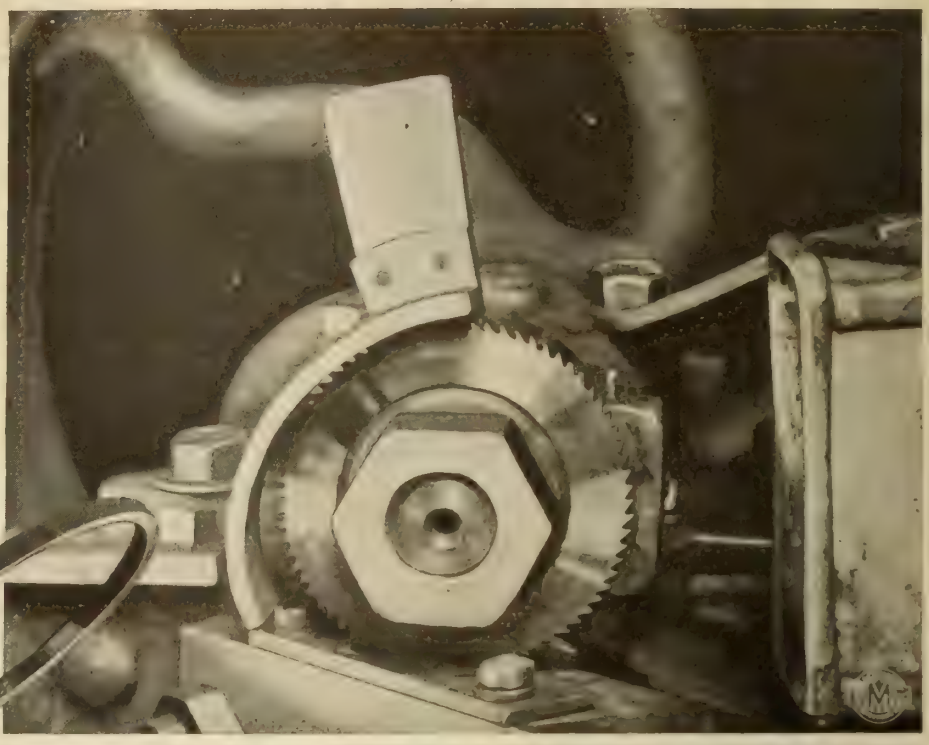
GTD *Little Stories of Real Production* GTD

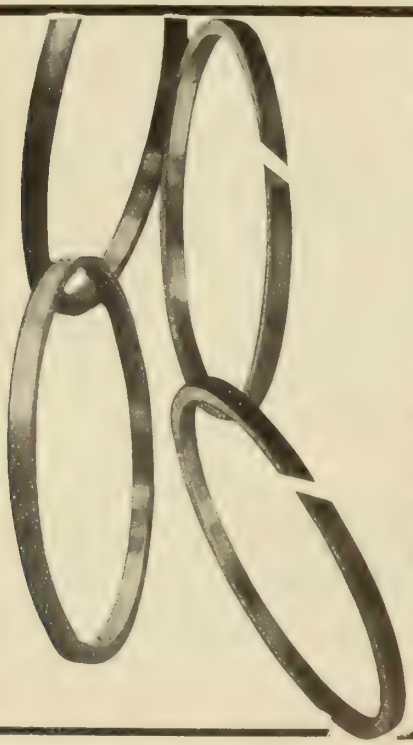
GTD

High Speed Slotting Cutters

REG U S PAT OFF
GTD
"MEANS PERFORMANCE"



Seven Times the Output Between Grinds



Manufacturers of piston rings are enthusiastic endorsers of GTD High Speed Slotting Cutters. Even those familiar with the performances of GTD Threading Tools, Drills, Reamers, etc., are amazed at the length of time GTD Slotting Cutters hold their edge.

One of these customers reports a maximum of 3,000 rings obtained with carbon cutters previously used against a minimum of 20,000 rings cut with GTD cutters; and accompanies it with an order for more of the same brand.

GTD Cutters will give you a lowered tool cost per work produced, and greater productive machine time. Changing tooling equipment is a big factor in lowering productive machine hours. Reduce it to the minimum.

GTD Quality is a standard recognized wherever big production and high grade workmanship are in demand.

You'll find GTD small tools to fit your every need described in our new catalog No. 46A. Write for it.

Where they tap nuts by the ton

Records Are Kept of Tap Performance

These show that Pratt & Whitney Taps score highest on two counts. Time between resharpenings is longer than ordinary. They can be sharpened and resharpened and still retain their original size long after other taps have gone to the scrap pile.

The "Con-eccentric land," an exclusive Pratt & Whitney feature — coupled with superior workmanship and rigid inspection both of the steel and the taps — are the secret of their long life.

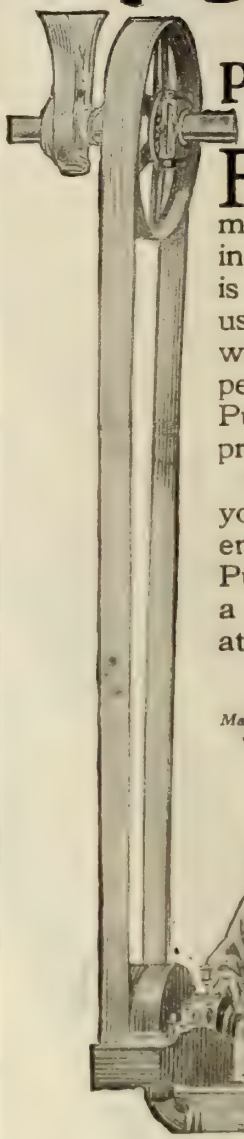
AMERICAN STEEL SPLIT PULLEYS



Prevent Vibration

PULLEY vibration eliminated, the life of bearings and machinery is lengthened—shafting is kept in alignment—power is conserved and made to do useful work instead of being wasted and lost. The practically perfect balance of "American" Pulleys assures true running—prevention of pulley vibration.

What you should expect from your pulleys is told in a book entitled, "Getting Maximum Pulley Efficiency." On request, a copy will be mailed to you at once.

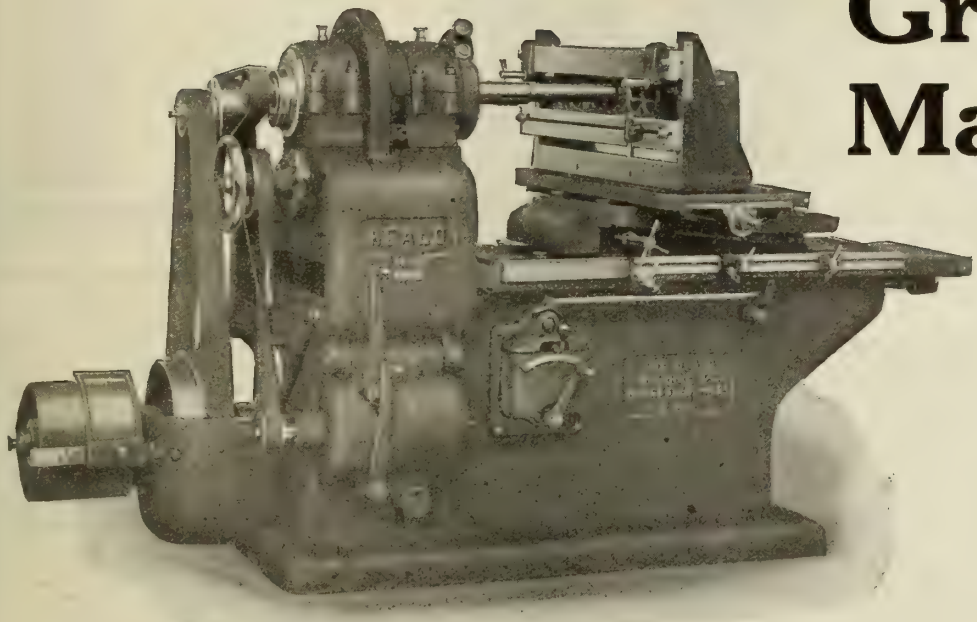
The Last Word on a Cylinder Grinding Machine



HEALD
Style No. 50

Simple — Massive
Large Capacity
Self Contained
Wide Range of Speeds and Feeds

The HEALD Style No. 50 Cylinder Grinder is an ideal machine for both the manufacturer and the repair shop. It is unusually massive, simple to operate, and has a hydraulic drive for the table instantly giving any speed desired, enabling the operator to get an unusually fine finish. With this drive it is possible to reverse the table at any desired point without shock or noise.

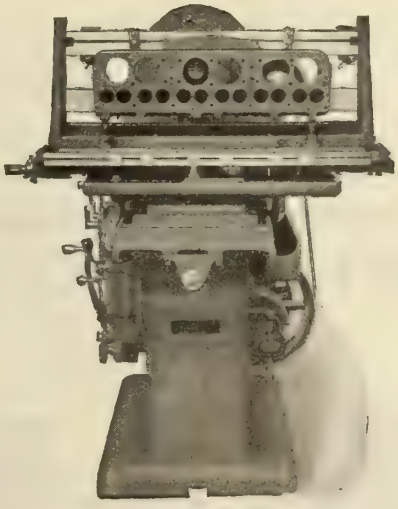
In addition to the adjustment secured by the HEALD Universal Locating Jig, there is sufficient vertical movement of the cross-slide table to take care of any slight vertical adjustment required after the bloc is in place. The head and spindle of the machine is similar to that which has been used so successfully for 17 years in all our other cylinder grinding machines.

The main driving shaft on the rear is mounted on ball bearings taking the power directly from the main line or motor.

The main and cross slide tables are unusually heavy, having extra wide ways, giving ample wearing surfaces and which are fully protected from grit and dirt.

Without doubt this is the finest machine tool of its kind on the market to-day, and whether you are a manufacturer and wish to add to your equipment or a repair man and expect to go into the regrinding business, this new machine is so far superior to anything of its kind you cannot afford to neglect looking into its advantages.

Let us send you our new bulletin No. 50 explaining it in detail.



Grinding a Hudson Super-Six. Notice the Massiveness and Width, Giving Great Rigidity.

The Heald Machine Co.

51 New Bond St. **Worcester, Mass.**

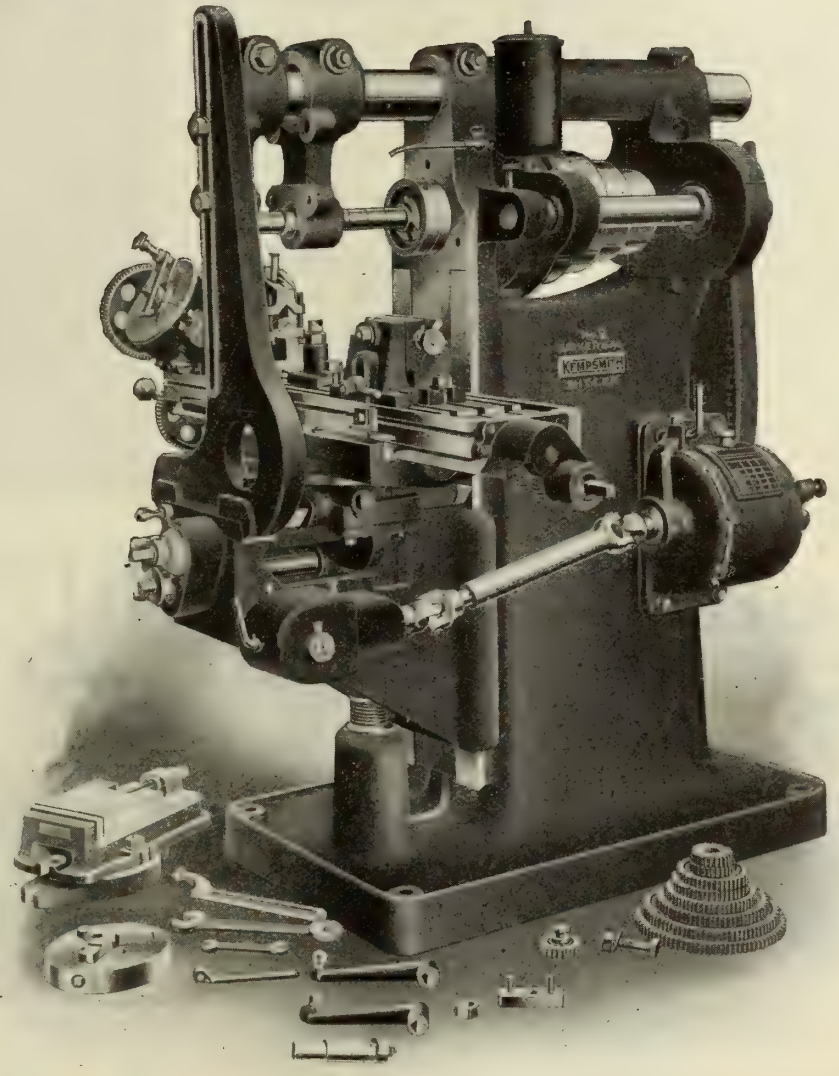
KEMPSMITH



No. 2 UNIVERSAL

Thirty-two years ago the Kempsmith Company began its career in a small one-storey frame building. To-day there are four main buildings, aggregating 106,000 square feet of floor area, besides various storage sheds, etc. Every building of the plant is a model of its kind.

It has always been, and will continue to be, the purpose of the Kempsmith Company to produce machines of the highest quality only, suited to the most advanced practice.

Every machine, whatever size or type, is put to test under cuts and conditions purposely more severe than it will encounter in even the most progressive shops and when it leaves our factory it has our positive and definite guarantee back of it.

Literature will be gladly sent upon request

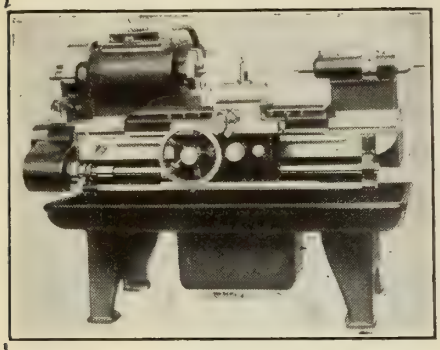
THE JOHNSON FRICTION CLUTCH

AS USED ON THE

"NEW" 12 IN. SUNDSTRAND MANUFACTURING LATHE



Progress in machine tool design demands a reliable and powerful friction clutch.

The Johnson Friction Clutch is proving of great value in machine tool designing.

Courtesy: The Rockford Tool Co., Rockford, Ill.

The main drive pulley is mounted on a No. 5 single clutch hub. The same movement that disengages the clutch automatically applies a brake which stops the spindle instantly. The sliding sleeve is machined to act as a brake.

A feature of the Johnson Friction Clutch is the ease of application to particular machine requirements.

Cleco Pressure-Seated Air Valves

Bowes Air Hose Couplings—Cleco Never Slip Hose Clamps — Cleco Grooved Hose Nipples and Hose Clamp Tool

STYLE O.F. is an Outside Thread Female Pipe End. Made in sizes ⅜-inch to 1½-inch.

STYLE I.F. is an Inside Thread Female Pipe End. Made in sizes ¼-inch to 1½-inch.

STYLE H.F. is a Female Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼-inch to 1½-inch.

STYLE H.M. is a Male Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼ inch to 1½-inch.

STYLE O.M. is an Inside Thread Male Pipe End. Made in sizes ⅜-inch to 1½-inch.

STYLE I.M. is an Inside Thread Male Pipe End. Made in sizes ¼-inch to 1½-inch.

The Male and Female Ends of Bowes Couplings interchange in sizes ¼-inch to ¾-inch. Sizes 1-inch and 1¼-inch interchange. The 1½-inch ends interchange only with themselves.

BOWES COUPLINGS

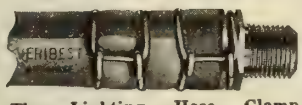
Are instantly connected or disconnected.
They are absolutely air-tight under all pressures.
They quickly pay for themselves by stopping costly leaks.
They interchange in sizes most commonly used.
They have no loose parts to be mislaid or lost.
They are made of brass and will not rust.
The U-shaped Gasket interchanges in couplings ¼-inch to ¾-inch.

CLECO AIR VALVES.

Style R.A. **Style P.O.** **Style A.**

Style P.O.—Made in sizes ¼ in., ⅜ in., ½ in., ¾ in., 1 in., 1¼ in., 1½ in., 1¾ in., and 2 in. Pipe Outlets. Inlets are one pipe size larger.
Style A—30° Angle Valves, are made in sizes ½ in., and ¾ in.
Style R.A.—Right Angle Valve, made in sizes ¼ in., ⅜ in., ½ in., and ¾ in.

CLECO GROOVED HOSE NIPPLES



Grooved Nipples when attached to the Hose with Wire Clamps as illustrated cannot "blow out." Wire clamp tool shown below applies the wires to hose.

The Lighting Hose Clamp Tool illustrated applies wire clamps at a cost of 1½ cents each.

In stock: Riveting and Chipping Hammers, Air Drills, Emery Grinders, Sand Rammers, etc.

Use Annealed Wire No. 14

IMPORTANT:—The Small Leaks in your "AIR LINE" mean serious loss in DOLLARS. Have you any idea of the amount of "Air" wasted in small leaks at your connections? Air Leakage through 1-16 in. opening equals 5.32 cu. ft. per minute at 80 lbs. It will pay you to install Bowes Couplings and Cleco Valves, which will stop costly leaks.

Bulletin No. 50, mailed on request.

THE MODEL HOSE LINE illustrated shows correct styles of couplings and valve to use and proper way to attach the Cleco Never Slip Hose Clamps to Bowes Couplings. No "blow-offs" can occur when "Cleco" Clamps are used.

"Shooting" the Man from Glengarry

THE Ottawa Valley has witnessed scenes during the past few weeks which have never before greeted the eyes of the dwellers within its limits. Realism—the sinewy log drivers, cleverly and daringly facing the camera; beautiful women rescued from the river's icy waters—terrific raft fights—log jams, where lean river men stepped from the playing of a part into real life—lumbermen armed with peevies and pike-poles, striving to break the menace of locked logs—all these are features of the most stupendous Canadian story yet filmed within the borders of this Dominion.

Ernest W. Shipman has been producing "The Man From Glengarry," Ralph Connor's masterpiece—and filming it with all the fidelity and accuracy which modern ingenuity can command. Those who have been privileged to witness these scenes have watched in action pretty, vivacious Mayme St. Clair, Bully Lenoir and Big MacDonald, reproducing the action contained between the covers of Ralph Connor's dramatic work.

Archie McKishnie has recently spent several days with Mr. Shipman's company and has told the story, in

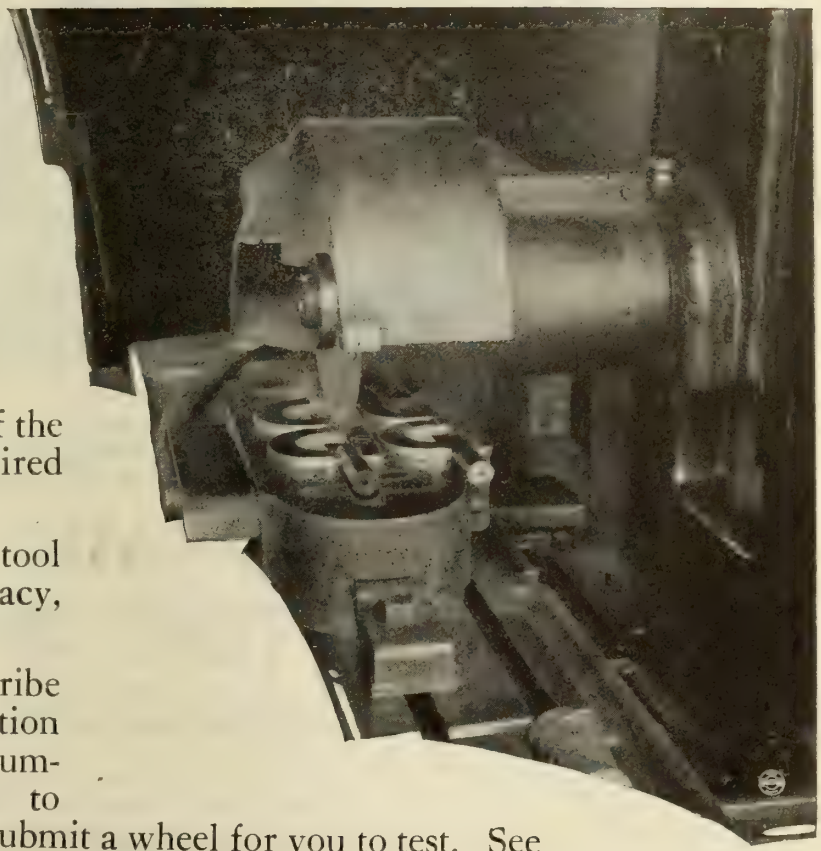
Norton Grinding Wheels

For Accuracy and Economy on Precision Work



For plane surface grinding, external cylindrical grinding, or internal cylindrical grinding, the specified limits, plus or minus, must be maintained.

With the proper machine and a Norton grinding wheel, with the abrasive, grain, and grade of the proper selection, the required results are assured.

The grinding wheel is a tool on which depends accuracy, production and economy.

Drop us a line:—Describe your particular job; mention make of machine and number of thousandths left to grind; we will be glad to submit a wheel for you to test. See how much you can reduce your grinding costs.

BROWN & SHARPE
AUTOMATIC
GEAR CUTTING MACHINES

For the Accurate Duplication of High-Grade Gears

The accuracy and precision of Brown & Sharpe Automatic Gear Cutting Machines are important factors in accurately duplicating high-grade gears. The high quality of these machines takes on an added importance with the introduction of the Ground-form Gear Cutter mentioned in a recent issue.* The full benefits of these Ground-form Cutters are assured by using them on Brown & Sharpe Gear Cutting Machines, whose highly accurate indexing mechanism gives the uniformity in spacing essential for the exact duplication of very accurate gears.

The extremely accurate worm wheel used on these machines is of large diameter in proportion to the diameter of the work, insuring accurate spacing of the gear teeth. The indexing mechanism operates without shock, has a positive start and stop, and is securely locked for each tooth space.

These high-grade machines are built by men whose one thought is to get things "right." Every detail of construction is subjected to rigid inspection and the machines leave our plant ready for a long life of accurate production.

Send for Catalog No. 137 describing these machines

Getting Service and Output From Sawing Machines

Angle, Set and Pitch of Teeth Must Be Right—Blades Should Have Proper Working Tension—Inserted Tooth Cutter—Intricate Shapes Produced on Shaping Saw

By J. H. RODGERS

EFFICIENCY in the cutting of metal by means of the sawing process requires a more thorough knowledge than one would at first suppose. The extent to which this method of metal cutting is now practised by the use of the hack saw, band saw or circular saw is the result of long experience in the development of improved steel and machine equipment. As any system of sawing is an evolution of the ordinary hack saw a few remarks on their handling and maintenance may be of interest.

The proper dimensions of saw blades should receive careful attention as it is very important that length, width and thickness be properly balanced. If too thin for length and width the edges become slack when strained in the frame, often resulting in crooked sawing or broken saw blades. On the other hand, if too thick unnecessary pressure is required to cut the metal.

Size and Shape of Teeth

The greater the number of teeth to an inch the more pressure required to cause a hack saw blade to cut. Thick, wide blades are made for heavy rapid cutting and should have coarse teeth as these require less pressure in cutting, do not clog easily, and are less likely to overheat and draw the temper from the points of the teeth. The angle of the teeth should be as great as possible for combined strength and speed of cutting.

Some mechanics believe that the finer the pitch of the teeth the longer the life of the blade. The pressure required to cause a saw to cut is in harmony with the area of its points, which area increases as the points become dulled. Fine teeth hack saws are legitimately demanded upon very thin stock sharp corners and tubing with thin walls. If the teeth are not combined with abnormal thickness they will stand a limited amount of abuse in excess of larger teeth, therefore they cover careless, and unavoidable awkward sawing to a limited degree.

Set of the Teeth

The object of set is to provide side clearance to the blade while cutting. This clearance is reduced as the teeth wear, therefore it should be sufficient to maintain ample freedom so as not to wear away in advance of the normal dulling of the blade. The diagram below is intended to represent a section of blade and several teeth.

If pressure is applied at A the resistance will be very great; the other points B, C, and D will decrease in resisting value according to the angle of inclination from the body of the blade. Consider B as representing the set of 10 pitch teeth, and C as representing the set of 14 pitch teeth. B has a greater resisting angle than C, therefore 10 pitch teeth of a certain thickness of blade carry a better set angle than a 14 pitch blade of the same thickness. If teeth are over set the angle of set becomes unfavorable. Small teeth combined with excessive thickness are bound to give a weak angle of set. If the body of a saw is extraordinarily thick for the size of teeth a proper amount of set cannot be obtained without injuring the structure of the metal.

Straining the Blade

One of the causes of frequent breakage is the way the blades are held in the frame. Hack saws should only be strained sufficiently to keep them taut. A saw strained to nearly the breaking point often breaks when placed in operation due to the additional strain of

Cuts 1 and 2 through courtesy of Newton Machine Tool Works. Cuts 3 and 4 by courtesy of Peerless Machine Co.

pressure applied. Some hack saw blades are made quite flexible by making a portion of the blade back of the teeth soft. This is done so that it will stand up against hard usage. This type of blade, however, although serviceable in many ways, has its disadvantages. They are not entirely suited for machine sawing as the tendency is to cut an irregular path owing to the lack of rigidy and temper in the blade. Chips will sometimes embed in the blade and cause breakage.

Similarity of Cutting Tools

In order to properly cut metal, the cutting tool must be provided with top, front and side clearance. Lathe tools, planer tools, milling cutters, twist drills, reamers, etc., all have three clearances. Hack saw teeth are metal cutting points, therefore the three clearances are necessary. Top clearance is provided and when worn away by use, cutting ceases. If front clearance is not provided, sawing is resolved into scraping, just as it would be in lathe and planer work. If side clearance is lacking through imperfect setting side friction is excessive, resulting in undue wearing away of the set, causing the generation of unnecessary heat, which tempers the points of the teeth, and the holding up of the blade causing slippage.

A common fallacy is to judge of the value of hack saw teeth by their speed of cutting. Slim weak teeth cut rapidly but owing to breakage, lack endurance. A correctly designed blade has proper cutting speed coupled with endurance. A machine with a 6 inch stroke causes the blade to travel six inches forward and six inches backward or one foot per stroke. Example, 60 strokes per minute times one foot equals 60 ft. per minute saw speed, which is sufficient for unannealled tool steel in wet sawing, 120 ft. per minute is sufficient for soft stocks, wet sawing, 80 ft. per minute for cast iron, which should be cut dry on account of slippage after the teeth become slightly dulled. When smoke is generated it indicates too high a speed.

The successful use of hack saws, whether hand sawing, wet or dry machine sawing depends upon the proper blending of the two controlling factors of speed and pressure. If a machinist revolves work in a lathe too rapidly, the work heats the cutting tool and lowers its temper and the tool refuses to cut. The remedy is to revolve the work at a less speed. The principal of cutting metal in a lathe and sawing metal is one and the same. If saw teeth dull unduly it is proof that the points of teeth are being tempered. They are over speeded. The remedy is to run the saw fewer strokes per minute. If saws or teeth break it is proof that pressure is excessive. In lathe work the softer the metal the more rapidly it can be fed to the tool. In sawing, the softer the metal the more rapid the saw can be run. Pressure is necessary to cause saws to cut; sharp saws require less pressure than dull saws. The proper pressure to cause a dull saw to cut will cause a sharp saw to hog in and break. Soft stock and small stock require less pressure than hard stock and large stock. Thin saws require less pressure than thick ones. Breakage is proof of too much pressure.

A common error is to use too much pressure with sharp saws and too little pressure with dull saws. It is good practice in starting new saws to use them under light pressure until the points are slightly dulled, after which the pressure can be freely increased.

Factors of Economy

Hack saws can be crowded well up to their tempering and breaking points and made to cut rapidly, in which case they will give a limited service, or they can be operated at a less rugged pace and they will give additional service. Hack saw machines are operated in two ways namely, allowed to cut without attention and attended. If unattended it is economy to save saws. If attended it is economy to save wages. It is not economy to carry saws to the point of breakage, nor to run them too fast with light pressure and glaze the teeth and cause slippage. Teeth can be tempered in both dry and wet sawing. It is simply a matter of sufficient speed and pressure. Sharp saws will stand a greater speed than dull saws. A sharp saw cutting successfully well up to the limit of speed and pressure will, when sufficiently dulled, temper its teeth and abruptly stop cutting. The safest formula for economical sawing is to keep well within the limit of speed and use sufficient pressure to keep the blade cutting. It is waste to enter the breaking zone.

Lubricate Saw Freely

In wet sawing under high speed many blades are entirely ruined by allowing the saw to cut in advance of the cooling liquid reaching the blade, or owing to the pump failing to function. A single stroke of the saw on hard metal is sufficient to soften the points of the teeth. The cooling liquid should be of ample volume and applied central upon the saw directly over the point of cutting.

Saw efficiency might be summed up briefly as follows: heavy machines break light blades; heavy blades refuse to cut in light machines; blades temper from over speed; blades break from over pressure; keep speed and pressure within limit; thick blades with small teeth have a weak set; loose blades buckle and break; over-straining breaks blades. Too high speed causes dulling; too great pressure breaks the teeth; make conditions conform to saw.

All beneficial instruction in regard to saw blades may have a negative value

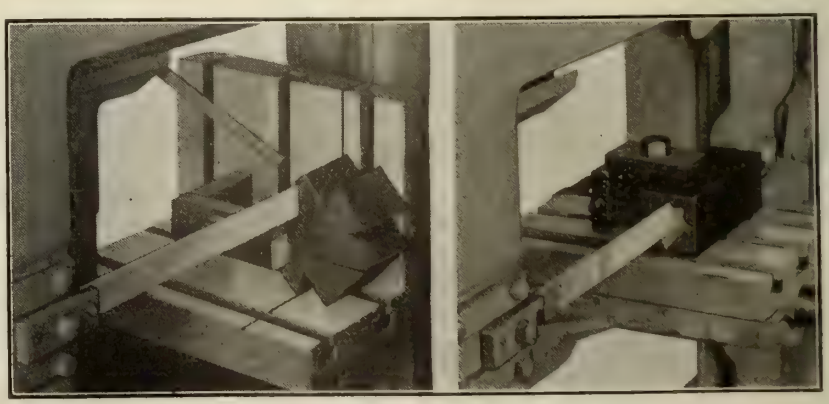

Fig. 3.—Cutting shapes on universal sawing machine.

if care is not given to the machines in which they are used. These should be kept in good repair and proper alignment to maintain the maximum production efficiency.

The remarks outlined for the use of hack saws likewise apply to band saws and circular saws. Various examples of the latter are used quite extensively in milling machines, and it is often difficult to distinguish between a saw and a cutter on this work, but the principles apply in all cases.

Large Cold Sawing Machines

Some examples of heavy duty sawing is shown in Fig. 1. The view on the left shows a 26-in. Newton cold saw cutting-off machine equipped with 22-inch diameter saws, cutting off 3¼ in. stock at the rate of 27 slugs an hour. The machines are equipped with air controlled clamps and stock trolleys which facilitate handling of material. When they are located in alternate positions one man can look after two machines. The rate of cutting here specified gives economic production for blades, although increased cutting speed can be obtained without overduly working of machines.

The view on the right illustrates an interesting operation for this type of saw. It shows a 32-inch saw working on the large crank shafts. The advantage of sawing these webs over the slotting method is the continuous cutting of the saw. The staggering of the cutters permits of maximum cutting at normal speeds.

Grinding the Inserted Tooth

The accuracy of the setting of the inserted teeth is a very important part of production service. Special grinders and tooth holding fixtures enable the operator to obtain the greatest degree of efficiency when re-grinding the cutters, as the proper contour and size is always maintained. Various views of the sharpening process are shown in Fig. 2. At the lower left is shown the method of setting the stop block by means of the setting gauge. After dressing the wheel face, the gauge is placed against the wheel and the stop block lined up and clamped. The cutter is placed in holder and clamped in position, the amount to be ground off being regulated by the space B, adjustment being made by screw S. The top centre view shows a plan of this operation. Details of the grinding of the top of tooth cutter is shown at lower centre, while the method of dressing wheel is indicated at lower right.

Universal Shaper Saw

A more extended application of the hack saw to production work is shown in Fig. 3, where a universal shaper saw is used in producing work of an intricate character. The left hand view shows the production of drop forge die blocks by means of saw cuts. The illustration on the right shows the cutting of a double square from a block that previously had a hole drilled through.

This saw is operated on the crank and connecting rod principle and the draw or cutting stroke takes place when the speed is reduced to the minimum when the operating speed is the maximum suitable for the work being handled. On the return stroke the blade is relieved by action of a cam on the crank shaft. A similar cam on the same shaft operates the feeding mechanism. The rate of feed can be regulated by a small handwheel, through a spring that compensates for the resistance of the material being cut.

A special attachment is furnished with the machine for the accurate cutting of irregular shapes. The table is fitted with a cross feed. An idea of the range of this machine may be had from Fig. 4.

Fig. 4.—Some of the work produced on universal shaping saw.

NEARING DANGER IN COAL SITUATION

Enquiry of officials handling records of incoming freight in Toronto, shows that there is very little coal of any kind coming across the international bridges for Canadian consumption. "We have a few cars, say three or four daily, representing hang-over shipments, where formerly we would have trainloads," was a statement given to Canadian Machinery. It was added that, while there were fair supplies on hand, some concern was developing as to the future.

At the present rate of production and consumption, one month will bring the critical period: that is, the first or second week in August. According to Industrial Digest, this estimate is compiled from reports of the United States Geological Survey and the Department of Commerce. If production is not increased by that time, it is said, the factories of the nation will have to shut down for a day or two each week in order to conserve the coal supply.

Since April 1 the anthracite mines of the country have produced only a few thousand tons of coal. During that period they usually mine about 20,000,000 tons, nearly one quarter of the entire year's requirements. They are so far behind now that if work in the anthracite regions were to start to-morrow it would be impossible to turn out a full supply this year, even if the mines operated constantly at maximum speed and had a continuous supply of all the freight cars they needed to take the fuel away.

In the bituminous industry the non-union mines are running at a terrific rate, producing between 5,000,000 and 6,000,000 tons a week. One Wednesday in the middle of June they broke a record by producing more than 17,000 carloads—the largest single day's production ever turned out in those fields. But in spite of the best they can do the nation's weekly consumption exceeds production by about 2,500,000 tons.

The situation in the bituminous industry, according to government reports, has never been paralleled before. With the certainty of a shortage before them, the consumers of soft coal nevertheless delayed their purchases until the new freight rates went into effect on July 1. Up to that time coal accumulated at terminal points, clogging up transportation facilities.

In Alabama at the close of June there was so much non-union coal on hand that the bottom dropped out of the market. An order by the Interstate Commerce Commission permitting Alabama coal to travel into the Chicago market at a competitive freight rate with West Virginia coal brought thousands of tons north from Alabama, but left the Birmingham market still overloaded.

Now that the rates have been reduced a heavy demand is expected. New England, which has been holding off, will probably put its orders in, and the rest of the nation will do likewise. Then the shortage will begin to be apparent in the market.

SHARPENING CUTTING TOOLS

Cutting tools should be sharpened against their edges, according to a booklet "How to Sharpen." With certain exceptions all kinds of sharpening, both on grinders and oil stones, should be performed with the tool edge working against the stone. One exception is when the tool itself is held still while the whetstone or oil stone is moved to accomplish the sharpening. Sharpening against the edge results in a minimum amount of wire edge being left. Straight strokes are productive of quickest results.

Discuss Plans for Blast Furnace Industry

Meeting of Mining Men and Metallurgists Before Minister of Mines—Adequate Magnetite Ore Resources Available—Government Bounty or Other Assistance Towards Development—Competition With Natural American Ores Big Problem—Further Exploration of Ontario Range Advisable

THAT the known large iron ore resources of Ontario are sufficient to support an iron and steel industry, provided these ores are beneficiated.

We believe that extensive drilling and exploration of the known ranges may prove that existence of available ore resources that would not require beneficiation.

We believe that the market can absorb large tonnage of beneficiated ores if the price is satisfactory and that both magnetic separation and calcining of siderites are recommended.

Be it resolved that the Ontario Government be requested to appoint a special committee consisting of at least one geologist, one metallurgist and one transportation expert to prepare a report upon the various phases in connection with the development of the industry.

The above resolutions were the result of a meeting, the first of its kind, held before Hon. Harry Mills, Minister of Mines, at the Parliament buildings, Toronto, July 5, to consider various questions looking to the practical development of Ontario's iron ore deposits. The meeting brought together quite a representative gathering of metallurgists, geologists, and manufacturers, all more or less directly interested in the question.

The discussion was directed along lines calculated to bring out information relative to the extent of the iron ore deposits of Ontario, but also their qualities from a merchantable standpoint, and the procedure deemed necessary to make the product attractive to the market.

Large Deposits of Magnetite Ores

Under the heading, "The extent of the iron ore deposits of Ontario," the discussion was lead by C. W. Knight, Dr. W. H. Collins, and J. D. Jones, general superintendent of the Algoma Steel Corporation. It developed that from the Ottawa region on the east to the Superior region on the north, there were frequent deposits of varying quantity. Some hematite ore had been discovered, but not in sufficient quantity to encourage extensive industry. It was, however, pretty welll established that in magnetite and siderite ores the province had exceptional resources. Notable examples referred to were the Moose Mountain mine, where according to J. Roland Cox, the magnetite ores were briquetted, and the Magpie Mine of the Algoma Steel Corporation. Both of these mines are at present inactive. During the war period they had been operated to advantage, but at the present time could not compete with the ores from the Messabe range in Minnesota, and other well organized American ranges in Michigan and Wisconsin.

Must Have Assistance

A significant statement was made by George S. Cowie, secretary of the mines department, Algoma Steel Corporation, that they had never made a cent out of the treatment of low grade ores. There had been some encouragement while coal was available at $2.75 a ton, but when it advanced to $12, it was enough. That was one reason why they were not operating the Magpie mine. They had spent something like three million dollars treating low grade ores in order to keep so much money in Canada. They did not intend to make further expenditure in that direction unless there was government encouragement of some kind, say by way of bounty. Such assistance he said was all that was required to bridge the gap that now existed between the producers of the ore and its purchase and use by Canadian furnaces.

Mr. Jones pointed out that, after an investigation of American mining and furnace enterprises, there was really no unsurmountable difficulties in Canada. Taking a mixture composed say, of 60% siderite and 50% magnetite, he could produce an ore that was cheaper by $1.57 than anything they could get from the straight American ores. What was needed here was a special study of ore conditions in order to give the furnaces the grades of ore necessary to meet the requirements of customers. There were no problems or conditions in Canada that were not existing in United States, and were being solved there while here very little had been done in an organized way.

On the suggestion that an association be formed to develop an ore industry and place the same on a commercial basis, Col. J. A. Currie, Parry Sound Iron Co., stated that in the United States, the organization of the industry was such that the amount and prices of certain grades of ore for specific purposes were matters of definite knowledge at the opening of the placing period, generally the first of the year. All question of chance was eliminated. The first matter to consider was, what incentive existed to buy Canadian ores? What guarantee could be given as to grades of ore? In the United States this was a definite matter.

Can Ontario Ores Compete?

In discussing processes for increasing the metallic content of low grade magnetites, G. C. MacKenzie, secretary of the Canadian Institute of Mining and Metallurgy, came to the conclusion that unless beneficiated ores could compete with natural ore both in quality and

General view of the blast furnaces at the plant of the Algoma Steel Corporation.

price, the venture must prove unprofitable.

J. Roland Cox, Moose Mountain Mine, replied that they had proven at this mine that Ontario ores can be treated commercially. During the war they had shipped ore as far as Tennessee, and there was again a prospect of business from that locality. The beneficiated ores from Moose Mountain, he declared, were superior to anything he had heard of, either physically or chemically. As far as the meeting was concerned, the statement could be taken as positive, that, operating on a large scale, say two to five thousand tons, and using ores of 35% in iron, low in phosphorous and sulphur, Ontario could compete with the natural ores of the United States. A ton of such ore was worth more than a ton of Messabe, being much higher in iron content. As to processes of beneficiating magnetite ores, Mr. Cox was of opinion that, from recent developments, a direct electric process would be evolved that would be satisfactory in every way. Cheap electric power was bringing this within the range of possibility, and at the present time some important individual investigations were being made.

When U. S. Bought Canadian Ores

T. B. Caldwell, Lanark, expressed the opinion that, so long as the Canadian furnaces had an easy buying market in the United States, they appeared to be satisfied. Last year they had shipped in more than five million dollars' worth. It was time that Canadians took steps to become more or less independent in this regard by development of their own resources. The war had taught not only the necessity but the feasibility of further development of the furnace industry. He stated that the range at Temagami, within 300 miles of Toronto, was an example of the rich deposits available throughout Ontario. This brought from Mr. Kidd, Ottawa, who is interested in eastern properties the interesting statement that, in the early eighties, ore to the amount of half a million tons, had been shipped from the Ottawa district to Cleveland and Pittsburg. This ore was suitable for high grade steel and would still be shipped to the United States were it not for the fact that the American Government had imposed a tariff of 60% against Canadian ores. He asked Mr. Morrow of he Steel Company of Canada why such ore was not acceptable to Canadian furnaces. Such ore was being sold to Pennsylvania interests.

Home Market Available

Mr. Morrow replied that anything that was acceptable to the Pennsylvania people was acceptable to the Steel Company of Canada. He was inclined to the opinion that acceptable Canadian ores had never been offered. If it had, it must have been off somewhere. Not only had market prices to be considered, but what was of prime importance, the chemical analysis based on furnace requirements. Different ores produced different grades of pig. He was of opinion that Canadian ores were available, but not in sufficient tonnages. The Steel Company required from two to three million tons yearly, and this had to be available before the close of navigation. As marketed at present, different mixtures were actually delivered to meet different requirements of the furnaces. His company produced a larger variety of products than any in the world.

Discussing beneficiation methods, J. D. Jones stated that at the present time, to his mind, by far the cheapest method would be to treat ores so as to make them amenable to blast furnace practice. The re-designing and building of blast furnaces and plants, costing three or four million dollars, was far in excess of what the cost of a concentrating plant would be.

Plans For Assistance

Different plans of government assistance were discussed. A bounty of 75 cents per ton at the mouth of the mine, for a period of years, say 10 or 15, was regarded with favor. Another proposition was that the government should build and equip plants, scattering repayment over a series of years, as in the housing plan. It was suggested further that electric power might be made available at a low figure as in Sweden where the iron and steel industry has developed to huge proportions, almost as the direct result of such encouragement. It seemed agreed that until there was such assistance for the Canadian industry, no progress would be made.

The question of tariff on mining machinery was also touched upon. Mr. Cowie stated that when they were starting the Magpie Mine and were in the market for a certain kind of brick, they had to prove that such brick was not made in Canada. They did so, and the brick came in free. Shortly after that, a duty was slapped on and, he said, that brick could not be obtained in Canada to-day. Mr. Cox also pointed out, as an instance of the peculiar working of the tariff regulations, that he had purchased equipment similar to some used in the silver mines, but, because his was an iron mine, he had to pay duty.

U. S. Ores Depreciating

Hon. Mr. Mills pointed out that these were matters that could be taken up with the Dominion Government. The object of the meeting was to discuss the feasibility of a furnace industry. On this the meeting seemed unanimous that Canadians should develop such an industry, rather than have people come in from other countries to develop it for them. One factor that tended to eliminate the factor of an impossible competition was that deposits, in the United States, of the hematite ores were depreciating and that in ten or fifteen years the treat- of low grade ores would have become an absolute necessity. Already at Babbit, in the Messabe range, a plant costing four million dollars was being built for the treatment of the lower grade ores. But he had no doubt that beneath the deposits of magnetite ores in Ontario concentrations of natural ore would be found. He read an extract from a paper prepared by J. E. Marks, Port Arthur, to the effect that during the past 13 years, Canada imported iron and steel products to the value of about $1,235,000,000, all of which should have been produced in Canada. He said that Canada should be in a position to produce seven million tons of steel.

The question of transportation was discussed by representatives of C. P. R. and C. N. R. and the meeting assured that there would be sympathetic co-operation from that quarter.

J. N. McKendrick, Galt, president of the Belcher iron mines, located on Belcher Island, Hudson's Bay, stated that they had there a practically unlimited deposit of ore with metallic content running from 40 to 54%, which could be laid down at Cleveland to meet American competition, and which could also be made available to the British market, as he had learned that the passages through Hudson's Bay were not as unnavigable for as long a period in the year as the Hudson's Bay Company represented them to be.

OBITUARY

Shipbuilding and allied interests will regret to hear of the death of William Newman, supt. of wrecking for the John E. Russell Wrecking Co. of Toronto. Mr. Newman, who had gone to St. Catharines to superintend the reconstruction of the freighter Joyland, which he raised near Clayton, New York, a few weeks ago, was walking the deck of the steamer when he stepped into an open hatchway and dropped to the hold of the vessel, sustaining serious injuries. He was taken to a hospital but died two hours after admission. Mr. Newman was born in Kingston forty-nine years ago, and had been associated with shipbuilding and salvaging interests for many years. During the war Mr. Newman was commissioned by the U. S. Government through the Canadian Stewart Co., to superintend the installation of special bulkheads in the big ocean liners commandeered for troop transport. He held the record for the launching time of large vessels.

Cast iron remains a question in welding. According to some welders, the difference between perfect success in some instances of cast iron welding and failure in others lies in the various degrees of preparation for welding and treatment subsequent to welding. Cast iron not prepared by adequate pre-heating is apt to crack, and the crack does not always take place at the weld. For best results, the entire casting should be at a red temperature, though there are cases where partial pre-heating is sufficient.

Machining Locomotive Piston and Cylinder Head

Multiple Tooling Used to Advantage in Machining Small Quantities—Standardizing Machine Equipment—Combining Feeds to Obtain Tapers—Work Finished in Two Settings

By H. ALTON

MODERN railroad shop practice does not lend itself to the use of automatic and semi-automatic machines to the same extent that a straight manufacturing proposition does. Nevertheless, in most shops there are a number of turret lathes and other machines, with and without automatic features but carrying multiple tooling, that are used in regular work machining relatively small numbers of pieces, but doing so very efficiently. At a first glance, the tooling set-ups do not impress one with the idea that they are efficient when employed for short runs. The fact that such practice does pay under these circumstances, is due to the standardization of certain boring bars, tool holders, and small tools. In the hands of experienced men this form of equipment becomes very versatile. Many jobs can be set up quite as quickly as general work on an engine lathe or other standard machine. The two machining operations described in this article, were accomplished in a railroad shop on the Bullard vertical turret lathe with some of the standard equipment developed for this purpose. In these operations it will be seen that the varied feeds and speeds, as well as combinations of feeds that are available, helps to a great extent in the application of the tooling.

Machining a Locomotive Piston

The piston casting is held in a three jaw chuck in the usual way as indicated in Fig. 1. In the first operation, turning and facing are done simultaneously. There are two facing tools held in the bar extending from the turret. These tools take what constitutes a roughing and finishing cut with one traverse of the turret. While they are cutting, the tool in the side head is turning the outside diameter down to a point where the lower ring groove will be located. A complete turning is, of course, prevented by the chuck jaws.

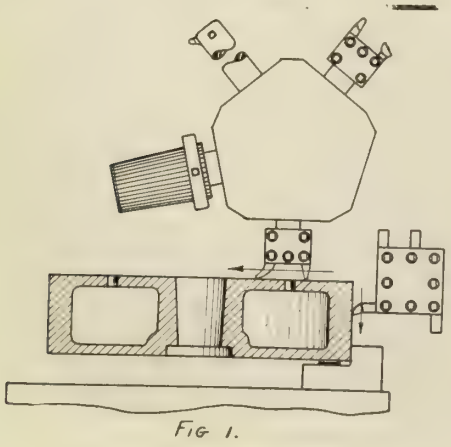

FIG 1.

Turning and facing piston.

After this work has been completed the turret is indexed and the edge of the piston is chamfered in the second operation. The tool is held in the turret and the proper angle of feed is accomplished by use of the vertical and transverse feed simultaneously. The angle is obtained by using certain index gears in combination with certain feed positions. As will be seen the round nose tool takes the first cut removing the major portion of the metal. It is followed by the square nose finishing tool held in the same holder. With the indexing of the turret, the operator also swings the side head around and brings into operation the two tools that rough out the grooves for the rings. While the chamfering is in progress the side tools are roughing out the grooves. These operations are shown diagrammatically in Fig. 2.

The third operation is shown in Fig. 3. The ring grooves are finished by the single tool in the side head, while the piston is rough bored by the tools carried in the turret. The taper feeding is here also accomplished by combining the vertical and transverse feeds. In Fig. 4 the fourth operation is illustrated, showing how the piston is finish bored and finish turned. In the fifth operation, shown in Fig. 5, the piston bore is reamed. A special reamer fitted with a stop collar is used. This latter fixture ensures that all bores will be machined to extremely close limiting diameters.

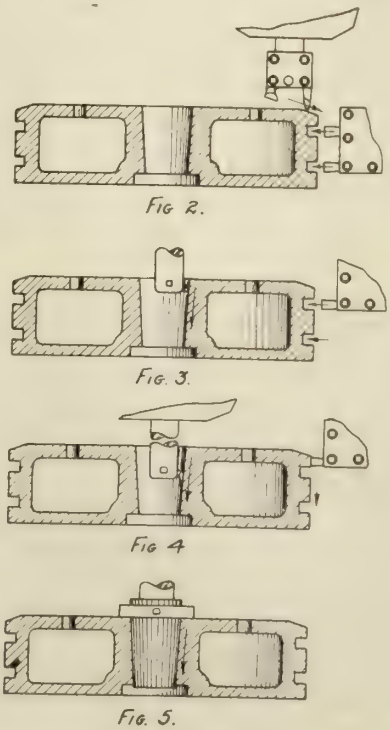

FIG 2.

FIG. 3.

FIG 4

FIG. 5.

Operations 2-3-4 and 5.

This operation completes the work done in the first setting.

The piston is turned over for the second setting, and is located and chucked as shown. In the first operation the turret tools rough and finish face while a double sub-operation is occurring simultaneously with the side head tools. These side head tools rough turn the remaining portion of the outside diameter, and then the edge is chamfered as shown in Fig. 6. The second operation is to rough out the counterbore with the turret tools and finish turn the outside diameter as shown in Fig. 7. The third and final operation is to finish the counterbore, which operation is sketched diagrammatically in Fig. 8.

Operations on a Cylinder Head

It will be noted that there is a certain general similarity between the tools used and their application, in this instance, and the ones used in machining the piston. This point illustrates the underlying fact that such equipment can be standardized and yet be used in a very general way. This cylinder head is machined practically all over—some surfaces being merely cleaned up for clearance. The head is chucked as shown in Fig. 9, special jaws being used. The

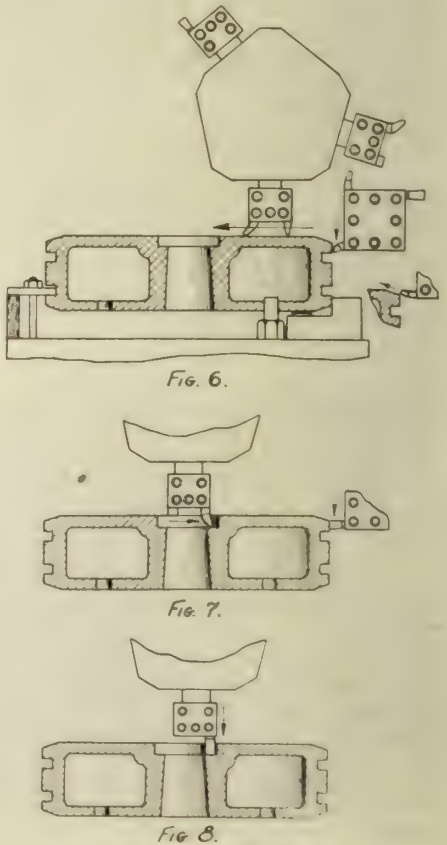

FIG. 6.

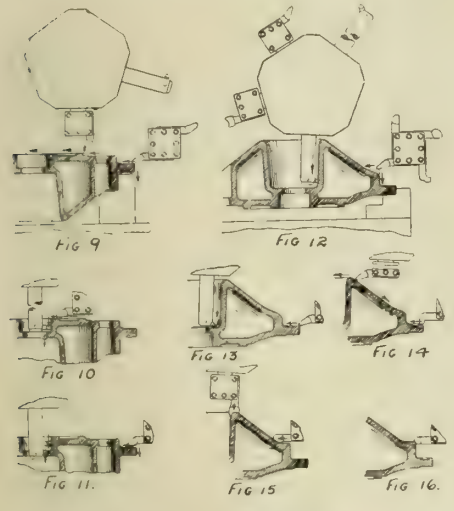
FIG. 7.

FIG 8.

Operations 6-7 and 8.

first operation is that of facing and turning as shown, both turret and side head tools being used. The second operation rough bores and rough counterbores the head with the turret tools, while certain finish facing operations are accomplished by the side head tools, as shown in Fig. 10. The bore and counterbore are finished in the third operation by the turret tools as shown in Fig. 11. At the same time the outer flange is finish faced, and the outside diameter finish turned by the side head tools. These three operations complete the work of the first setting.

For the second setting, the head is turned over and chucked as shown in Fig. 12. The first operation in this case is to rough bore the central recess with the turret tools and to turn and face the top surfaces with the side head tools. The taper attachment of the side head is



Operations on cylinder head.

used to obtain the necessary angular feeding. The second operation is to finish the taper bore, face the internal flange and form the fillet with the turret tools as shown in Fig. 13. While this is being done a side head tool is used to face the flange on the outside. The third operation is to finish face the tapered surface and square off the top surface by means of turret tools employing a combination of vertical and transverse feeds. While this operation is being done the side head tools are used to finish face the outer flange. These operations are shown in Fig. 14. The fourth operation is shown in Fig. 15. The top radius is formed by a turret tool and the shoulder is faced and the radius formed by a side head tool. The fifth and final operation is one of forming done by a side head tool, and shown in Fig. 16.

Machining Time

The time consumed in setting up and machining for one of these pieces compares favorably with that of engine lathe or boring mill performance, but when more than one part is to be put through, the saving in time becomes very evident. The stops on most of these machines can be set from gauges, test blocks, or even from the first piece.

Progress Report Of The Canadian Engineering Standards Association

THE progress made by the Canadian Engineering Standards Association, Ottawa, was presented and discussed at the last meeting held. Following are some of the interesting things commented upon.

Regarding the work of the sub-committee on the Canadian electrical code it was decided to forward to the minister of trade and commerce a memorandum outlining the present situation in regard to this question, and requesting him to convene a meeting of representatives of the various provincial governments, to discuss the possibility of interprovincial agreement and to acquaint the provincial governments with the difficulties now experienced by the industry. The following resolution was unanimously passed:

"Resolved that the memorandum on the proposed Canadian electrical code be approved, and that the secretary be rected to forward it to the minister of trade and commerce, calling his attention to the unsatisfactory situation at present existing in Canada due to the lack of uniformity in the requirements for electrical appliances and construction in the various provinces, and requesting the minister to consider the advisability of calling a conference of representatives of all the provincial governments with this association to discuss the matter with a view of obtaining interprovincial agreement and action." On the suggestion of Mr. Mountain it was decided to form a committee to consider the desirability of formulating standards for crossings of water and other pipe lines under railway lines.

The secretary reported that in response to an invitation received from the American Engineering Standards Committee, Mr. John Murphy, electrical engineer, board of railway commissioners, had acted as the representative of the C. E. S. A., in attending a conference held in New York to discuss measures to be taken in the United States with a view of obtaining uniformity in specifications for overhead crossings of electric lines over railways. This question in Canada is largely under the jurisdiction of the board of railway commissioners, and in order to obtain as far as possible an agreement between the requirements in force in Canada and those proposed in the United States it has been arranged that the American proposals, before their adoption, shall be forwarded for consideration and comment to a C. E. S. A. committee which is to be organized for that purpose. An invitation from the A. E. S. C. to take in a conference regarding colours for traffic signals was received. It was decided to thank the A. R. S. C. for this invitation, and to enquire whether a method of dealing with the matter similar to that adopted in the case of overhead crossings would be satisfactory to the A. E. S. C.

A suggestion from Mr. H. G. Bertram of the John Bertram and Sons Co., Dundas, was laid before the committee, outlining a scheme for the development of dimensional standards in Canada in connection with machine tool building. The committee expressed the opinion that action along the lines of Mr. Bertram's suggestion was very desirable, and the matter was referred to the chairman of the sectional committee on machine parts with a request for action if possible.

On the motion of Dr. Porter, seconded by Mr. Mountain, it was unanimously resolved that Mr. H. H. Vaughan be appointed chairman of the C. E. S. A. in succession to the late Sir John Kennedy. Mr. Vaughan expressed his willingness to accept the position and pointed out that, in his view, the thing which was now most necessary for the success and growth of the C. E. S. A. was the encouragement of the effective interest in the work of the association on the part of the manufacturing and industrial industries, this support being just as important and advantageous as the assistance rendered by engineers or scientific and technical societies. The election of Mr. Vaughan as chairman requiring the appointment of a second vice-chairman, Messrs. T. A. Russell and D. H. McDougall were unanimously elected as vice-chairmen, together with Dr. J. B. Porter as honorary secretary-treasurer, these gentlemen, with the chairman, forming the executive committee. The meeting of the main committee was followed by the fourth ordinary general meeting of the association, at which the annual report on the progress of work was presented, together with the auditor's financial statement for the year.

BOOK REVIEW

Modern Plumbing Illustrated is the title of a book recently offered by the Norman W. Henley Publishing Co., of New York. The author of this book, R. M. Starbuck, is one of the leading authorities on this subject in the United States. The book is of high standard and has been adopted as a reference book by many leading manufacturers and institutions in many countries. The book contains 407 pages (7½x10½) and treats in a comprehensive manner all problems relating to plumbing installation. Seventy full page plates drawn especially for the work, each plate having from four to eight pages of descriptive text. It is a helpful treatise to master plumbers and manufacturers in the science of sanitary plumbing. Price $5.00.

Montreal Tramways are importing from the mills near Chicago considerable tonnages of street railway rails. These are carried very largely on decks of grain carriers.

Machining Flange Coupling on Turret Lathe

Successful Production Largely a Question of Tooling—Difficulties Easily Overcome—Using Coarse Feeds—Overhead Support Aids to Rigidity—Simplicity of Design

THE USE of auto-lathes on chucking work which can be put in hand in quantities of 50 or more pieces at a time provides a well-tried and certain method of reducing production costs. Many firms who appreciate the saving which can be obtained by the use of auto-lathes have, however, been deterred from installing them by the fear that they would not get the best results from this class of machine on account of imaginary difficulties in tooling.

The auto-lathe is, in reality, a turret lathe in which all operations, save chucking, are automatically performed and one operator can, in consequence, look after a number of machines, so that the labour cost per machine hour is lower than on the combination turret lathe, although the production times may be the same.

The designing and laying out of tools for auto-lathes presents no difficulty to anyone having experience in tooling up turret lathes. The object of the present article is to examine the tooling on an article such as a standard flange coupling, which will show that the difficulties in tooling up auto-lathes are more imaginary than real.

Fig. 1 shows the lay-out for the first operation on the auto-lathe, this drawing giving the dimensions of the finished work-piece. At this operation the work is gripped by the boss in an 18-in. "Coventry" chuck fitted with a spring steady bush for the boring bars. A detailed view of this spring steady bush is inset in Fig. 2, which shows the set-up for the first operation.

The order of the tools can be followed from the lay-out, the first tool to be applied being the standard slide facing tool No. 1, which is brought up into position and held stationary by the standard retaining cam. The front cross slide No. 2 now feeds in, carrying a facing tool and a pusher which moves the slide facing tool transversely. Slightly behind the rough facing tool on the work the facing tool No. 3 comes in and finishes the face.

During the facing operations it will be noticed that there are four tools cutting simultaneously, and as they are operating on a rough casting there is considerable stress on the slide facing tool. To neutralise this, the base of the slide facing tool is tied up rigidly to the headstock by means of a vertical bracket integral with the base, this bracket being fitted with a bush which steadies on the overhead supporting bar carried on the headstock. This novel feature, which has been recently introduced on the slide facing tools ensures absolute rigidity and makes it possible to use much coarser feeds than could be employed previously.

The next tool to come into operation is a standard combination tool No. 4, which carries a boring bar for roughing the bore, a turning cutter for roughing the flange and a second turning cutter for roughing the spigot. This is followed up by a similar tool No. 5 for finishing the exterior of the bore and for sizing the spigot. Both combination tools are steadied by the overhead support as well as by the boring bar. The bore is finished to size by means of one of the standard Herbert boring bars with adjustable floating cutters.

At the second operation, Figs. 3 and 4, the method of chucking is particularly interesting, as it shows how concentricity between the two operations is ensured. A detailed view of the chuck

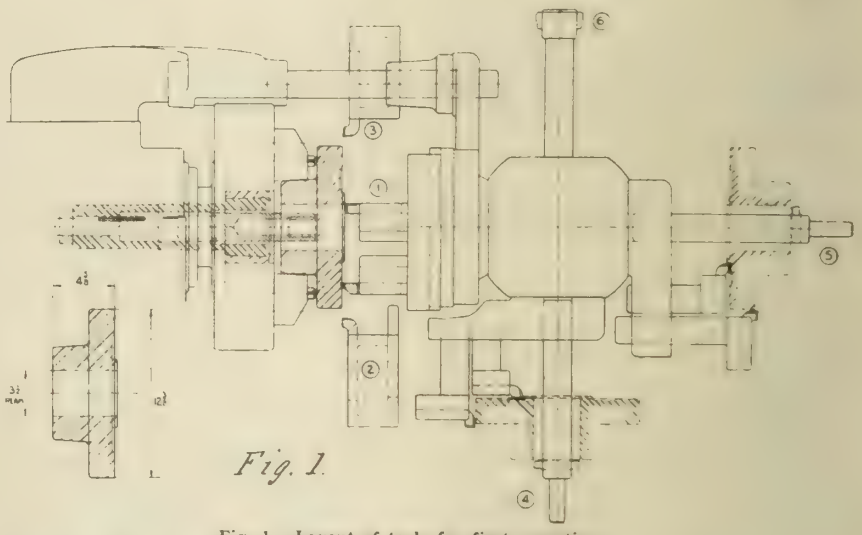


Fig. 1.—Layout of tools for first operation.

Material supplied through the courtesy of the Alfred Herbert Co.

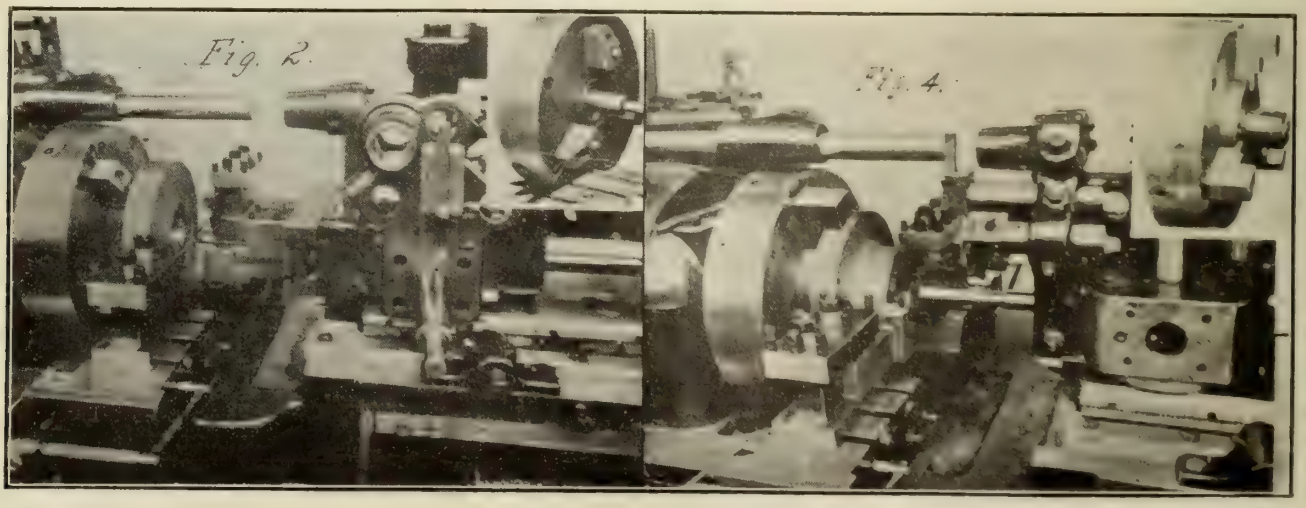

Fig. 2.—Set-up for first operation. Fig. 4.—Set-up for second operation.

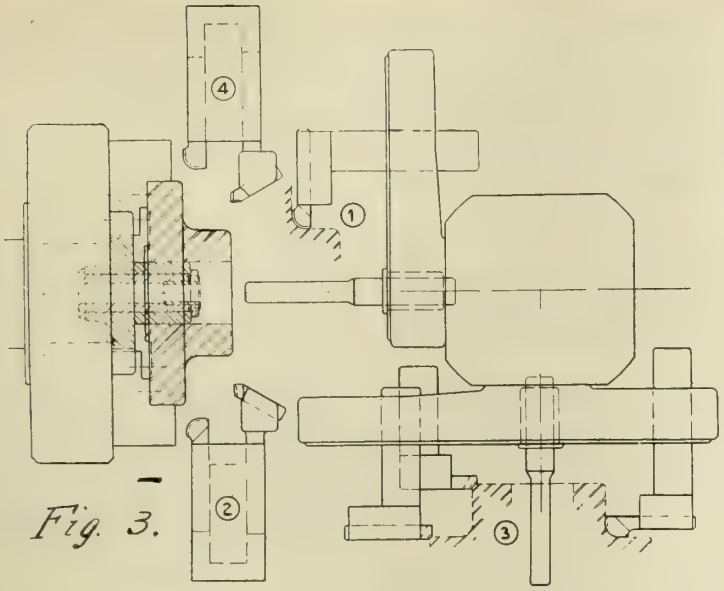

Fig. 3.

Fig. 3.—Tooling layout for second operation.

with the work removed is inset in Fig. 4, and shows the special locating plate which is bolted to the chuck. This is centred in the bore of the chuck by a spigot, and carries removable hardened locating plugs which are a sliding fit in the bore of the couplings. The work is gripped and driven by means of soft jaws bored out true, but the concentricity is ensured by the true central plug and not by the soft jaws.

The tooling of this operation is fairly simple. No. 1 is a combination tool carrying a cutter for turning the boss and simultaneously with this tool the front cross slide No. 2 comes in with two tools for rough facing the boss and shoulder. Nos. 3 and 4 are finishing operations on the same surfaces, but the combination tool No. 3 carries two additional cutters for forming the radii on the boss and the flange.

The total time for machining the complete piece, i.e., two operations, is 53 minutes, and couplings machined by this method run true when mounted on a test bar.

In the operations described the slide facing tools and two combination tools are part of the standard outfit of tools which obviously come in for a large variety of work, and in all cases it will be noticed that the cutting tools are of the simplest possible type, whilst the boring bars will probably be already in the tool stores of most works.

On the latest type of Auto-Lathe—the No. 5—setting-up is so much simplified that it is found quite profitable to machine quantities of 24 at a time on suitable work. We have a battery of auto-lathes running in our own works which we should be delighted to show our friends at any time by appointment. We have no doubt of our ability to convince them of the savings which can be effected by the installation of this type of machine.

Inspection And Inventory System At Hamilton Gear And Machine Plant

THE subject of inspection is always an interesting one. The Hamilton Gear and Machine Co., Toronto, are firm believers in careful inspection; and following are some methods in force which ensure the quality of material going into their various products.

They inspect the rawhide cylindrical blocks used for making their rawhide pinions, using a Brinell machine and taking reversed readings as follows:—The machine is equipped with a direct reading depth measuring device to indicate the depth of the impression made by the ball. They press the standard ball into the rawhide block, edgewise of the laminations, same way as the load is applied to the pinion tooth, indenting it a definite amount, and read on the dial the pressure used. By doing this they read the load bearing ability of the sample, for everything else is a constant but the load. Several samples are always inspected out of every shipment received.

They are always very careful with their steel castings and inspect them with a microscope, examining polished and etched specimens about ⅝ in. in dimension which are cut from the edge of the rim of the gear casting by two oppositely sloping hack saw cuts. This removes a piece in shape a triangular pyramid. After filing flat and polishing to a mirror finish, it is etched with an alcoholic solution of sodium picrate, which shows up the grain structure very plainly under the microscope and makes apparent the quality or defects in annealing or heat treatment. In this way it is possible to quickly and cheaply foretell whether the material will pass tensile test and it can be re-treated before any machine work is done on it.

"Mere softness as indicated by file or cutting tool is no indication at all that annealing has been properly done," says Chester B. Hamilton, Jnr., president of the firm. "The crystalline structure of steel may be very bad indeed and still machine nicely. No one who has not examined good and bad steel in this way with a microscope can have an idea of the great difference in the interior condition, i. e. the quality that counts. It seems like a fairy tale to say one can open a window in the side of a steel casting, look inside and see how well it was heat treated, whether it is strong and what percentage of carbon it contains and whether it contains impurities, yet it can be done in this way."

Mr. Hamilton is also interested in inventory and overhead, and states that as they do not manufacture for stock, but are in general a contract shop, their inventory is handled differently from a manufacturer's. They work up the value of the work "in process" from the individual time slips and material slips which bear charges against the various shop orders on which they are working. These slips are collected daily, used to check the workmen's clock record for the previous day, and priced and filed under the order number. Thus it is simply a matter of addition to find the value of the work in process. This would be a big job to do by hand and an adding machine is used for this work.

They distribute their overhead on the machine hour rate system, the total being so divided that each machine bears a share proportioned to the total as its installed cost is proportioned to the total value of running machines under average operating conditions. Thus, suppose one machine was worth one per cent. of the total, and the shop was operating on the average two thirds busy as measured in values of machines running. Then this one per cent. machine would bear one and one half per cent. of the overhead, and some other larger machine worth four per cent. of the total would bear 6 per cent of the overhead.

They do not follow this plan out absolutely, as they find it advisable to increase the rates on some machines which are chronically overloaded, and reduce them on some for which it is difficult to find work, but the above is the basis.

It is good practice to keep pneumatic hammers hanging in a tank of kerosene when not in use. This cuts all grease and dirt that may have accumulated. Don't lay hammers on the bottom of the tank as there they will catch the dirt. The kerosene in these tanks should be filtered frequently.

Some Notes on Hardening Various Screw Gauges

Results of Experimental Work—Effort to Obtain Process That Will Eliminate Warpage and Change of Shape—Methods of Heat Treating and Quenching Expansion and Contraction

By F. A. LIVERMORE, M.I.M.E., M.I.M.

THE present article is written, not in any way as a complete treatise on the above named subject, but with a view to assisting those interested in the more rapid production of the hardened gauges which will pass the National Physical Laboratory test. The following particulars have been obtained from experimental work conducted over a period of six months, but there is still much to be done to establish figures for various brands of steel. The heat treatment has been controlled from the laboratory, but the gauges have been hardened with certain precautions, in the ordinary way in the hardening shop. Now the essential requirements of screw gauges, as far as they are affected by heat-treatment are:—

(1). They must not change in shape. (become oval).

(2). They must not change in size (increase or decrease in volume).

(3). They must retain good surface after treatment.

If a gauge changes in shape and becomes oval, grinding which is extremely difficult, is necessary or it is worthless. If a gauge changes in volume and becomes smaller, it is useless; if larger, "lapping" is necessary. A good surface, whilst not as important as absence of change of shape or size, considerably adds to appearance and value of the gauge. The object of this research was the production of a gauge, well hardened, accurate to size, and with a sufficiently good surface, so that it would not be necessary even to polish after hardening.

Composition of Steel

The first assumption was made—"Provided there is not internal strain in the steel used, it is reasonable to hope that all gauges made in cast steel will give similar results under similar heat-treatment." This was found to be partially correct when the steels were approximately the same composition. Different cast steels give different results. Some appear to shrink, whilst others appear to expand, but gauges made from the same bar of steel give practically identical results.

In the early stages of the work some difficulty was experienced, and a number of gauges scrapped, owing to their being made from different steels. As a result of this, it was decided that until definite results were established, each gauge should be analysed for carbon and manganese before heat-treatment. From a number of preliminary results on different brands of steel, one having a high percentage of manganese was selected because—

(a) The manganese content of the steel appeared to affect the volume changes in the steel.

(b) This particular brand of steel could be quenched in oil and a better surface finish obtained than one quenched in water.

The steel analysed gave the following results:—carbon, 0.96 per cent.; silicon, 0.19 per cent.; manganese, 1.20 per cent.; sulphur, 0.03 per cent.; phosphorus, 0.02 per cent.

Heating Furnace

The furnace used for heating the gauges need not be of any particular kind as long as the metal is not heated too rapidly and uniformity during heating is obtained. Some months ago, in order to improve the surfaces of gauges, a small furnace having a reducing atmosphere (coal gas) and a direct passage to the quenching tank was designed. From this furnace a number of hardened gauges having a very good surface were obtained. However—it was found that quite as good results could be obtained when hardening from an ordinary furnace. A small Richmond gas furnace is very suitable for the work.

Heat-Treatment

It is well known that steel expands more and more as the temperature rises, and since in gauge work no change in volume is allowed, the quenching must take place at the lowest possible temperature, i. e. least volume expansion, at which correct hardness can be obtained. Now in order to find this exact temperature, pyrometric curves of the steel were prepared and the Ac: (calescence) and Ar: (recalescence) points carefully noted. From these curves it was decided to harden gauges from a temperature of 749. deg. C.—this temperature is sufficiently high to provide a fair margin for the hardener and at the same time it will secure a well-hardened gauge. Gauges quenched from this temperature are quite hard and cannot be cut by means of a file.

Whale oil is used for cooling purposes. This of course must be at a fairly low temperature, say about 30. deg. C. In order to prevent undue oxidation of gauges taking place during hardening also during transference from furnace to quenching tank, it is necessary to keep them from contact with the air as much as possible. This is done by providing for a reducing atmosphere in the furnace by means of excess gas, and also arranging for the quenching tank to be as near as possible to the furnace.

Tempering Gauges

Gauges are tempered in oil at 260. deg. C. sufficient time being given for obtaining uniform temperature throughout the metal. The volume changes which take place in the steel during the above detail heat-treatment can be best followed from the results obtained. The gauges were measured for all dimensions in the tool room by means of a simple micrometer instrument and Millward needles. The top, effective and core diameters were supplied to the laboratory. The following figures were obtained from almost the first heat treated gauges:—

The gauges were slightly oval on some of the dimensions.

It will be noticed from the figures that the greatest change has taken place in their effective diameter. The true results are not clearly shown until after tempering. This change in the effective diameter results from one of two causes. Either it is due to expansion or oxidation. With regard to the former, as previously stated, the metal expands during hardening expansion takes place in all directions, so that in the case of the plug gauge the expansion of the steel causes an opening out of the threads, and a consequent relative drop in the effective diameter.

If the gauge be heated in an upright position and the design be such that

		Gauge Hardened		
Part	Nominal Size	Before Hardening	After Hardening	After Tempering
Top	1.2000	1.1992	1.2008	1.1998

		Gauge Hardened		
Top	1.2000	1.1992	1.2008	1.1999
Effective	1.2170	1.2170	1.2175	1.2169
Core	1.4641	1.4633	1.4650	1.4640

Part	Before Hardening	After Hardening	After Tempering	Measured Again Sept. 18	Measured Again No. 18
Top	1.1997	1.2009	1.1999	1.2000	1.2000
Effective	1.2170	1.2170	1.2160	1.2159	1.2159
Core	1.4640	1.4655	1.4647	1.4647	1.4647
Top	1.2000	1.2011	1.2002	1.2002	1.2002
Effective	1.2170	1.2170	1.2158	1.2157	1.2157
Core	1.4640	1.4652	1.4642	1.4641	1.4641

the weight of the metal above the thread gauge be large, the effective diameter does not drop so much, because during heat-treatment, expansion—(which causes opening out of the threads)—is partially prevented by the weight of metal pressing downwards. As regards oxidation, this also accounts for drop in effective diameter. However, much work has been done since the above figures were obtained and it has been found that if the above mentioned precautions are taken no oxidation will occur.

Now the sudden cooling of the metal during quenching prevents the steel from regaining its original size, and therefore until tempering has taken place there is considerable strain in the gauge owing to its tendency to get back to its former size. On tempering, this strain is done away with and the gauge resumes its normal dimensions. The sizes for machining of gauges at the present time are arrived at from the figures previously given (due allowance being made for shape of gauge) and the later successful work in overcoming oxidation. Final figures are now being obtained somewhat as follows:—

The above results, which as can be seen, come within the National Physical Laboratory's requirements, have all been obtained under ordinary workshop conditions. However, it is essential that the hardening be in the hands of a reliable man who will carefully follow instructions given him. The present article gives particulars for plug gauges only. Figures for ring gauges have not yet been finally established.

ELECTRIC WELDING OF SHEET STEEL PARTS

THE ADAPTABILITY of the spot welding machine to the joining of sheet steel parts has greatly aided in speeding up the assembly work on automobiles and other products made of light metal materials. The varied and rough service that autos are often subjected to, calls for maximum strength with minimum lightness. The safety of many lives depends on automobile parts being right to the last detail, particularly the brake mechanism, and the welding of parts must be properly performed. To this end these machines are constructed to accomplish their object in as perfect a manner as possible, and welding machines are usually built especially for the particular class of work they are likely to be called upon to perform.

The operation shown in Fig. 1 is the welding of brake camshafts on a Winfield electric welder, the material being of cold-rolled steel ¾ in. dia. at the point of weld. A strong and durable weld is obtained at a production rate of 125 welds per hour.

The capacity of the machine here shown is the welding of stock of from ⅜ in. to 1 in. round or equivalent sectional area. Current can be steped to suit the size of stock being welded. The circulation system is so designed that it is not necessary to break connections when changing dies. Machine is provided with adjustable stops to locate work in proper position. The machine requires a floor space of 40 in. by 54 in.

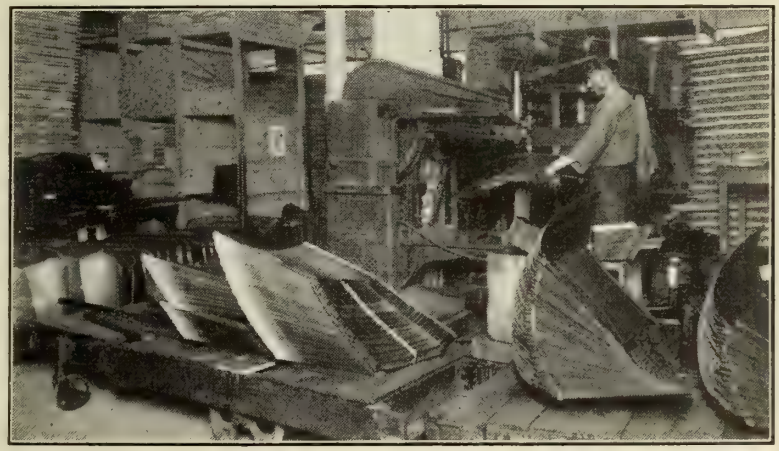

Fig. 2.—Assembly of automobile seat panels.

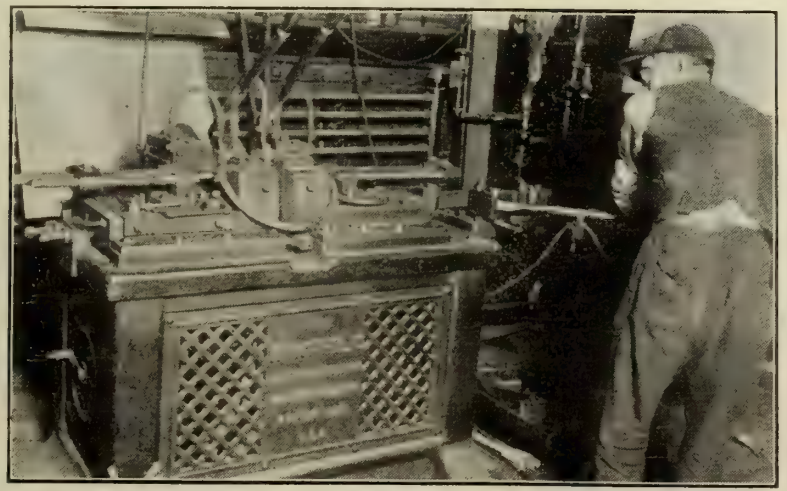

Fig. 1.—Welding automobile brake camshafts.

To protect the work from springing out of alignment the bed plate is provided with heavy tie rods.

The operation illustrated in Fig. 2 is the assembling of automobile seat panels, the welding being done on a Taylor machine. The work here shown is the joining of two pieces of No. 22 gauge sheet steel by means of 15 spot welds. The production rate is 800 panels—12,000 welds—per 9 hours, continuous performance. These machines have a wide range of application and require little skilled labor to operate.

No person should look directly at the flare of an electric arc or welding flame unless the eyes are protected with colored glasses, as the intense light is very injurious to the eyes.

News From the Welding Field

Mechanical Control of Oxy-Acetylene Torch

Cutting Metal by This Process Approaches Very Closely the Maximum Theoretical Efficiency—Obtaining Any Desired Shape By Means of Templates—Application of the Radiograph

By FRED J. MAEURER

WE have been trying for at least six months to have one of the largest companies in this territory to form a school of instruction for the operators of their plant, and held our first class this week. There were 35 operators present and six of the highest officials attended this class. We talked on care and maintenance of equipment, explained in minute detail the construction of regulators, torches and tips. This meeting lasted 2 1/2 hours and after it was over one of the heads of this plant told the writer that he thought this meeting was one of the best things he had ever attended. He also arranged that meetings would be held for all of the operators in this particular plant twice a mnth. There is no question that these meetings will effect a large oxygen and acetylene saving and also cut down their repair bills.

Radiagraph

The radiagraph is a portable, motor driven machine equipped with a 1-20 h.p. motor running 1,700 revolutions per minute, and can be set to travel or cut at twenty different speeds of from 1.5 inches per minute to 22 inches per minute, according to the thickness of the plate to be cut. The arm that holds the torch in place is so constructed that it is possible to move torch in or out, up or down, forward or backward and can also be set at any angle desired for bevelling plates. It was built for the cutting of straight lines and circles but with a little ingenuity it can be used for cutting of squares, ovals, and long irregular cuts.

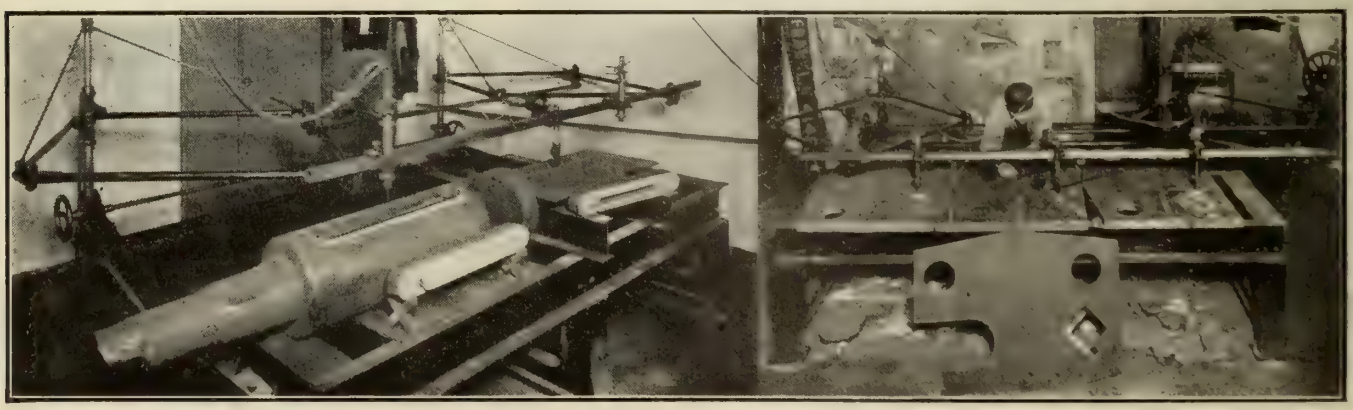
Fig. 1 shows a "close-up" of the finished cuts on plates also the machine, and we particularly call your attention to the smoothness and accuracy of these cutting surfaces. These slabs were cut into round pieces for forging purposes.

Fig. 2 shows the cutting of steel plates 2½ inches thick and 46 inches square as shown at D. The circles were used for flanges as shown at C, to be gas welded to steel shells 30 inches in diameter and 11 inches long. The outside cuts marked A were 45 inches in diameter, and inside cut marked B was 30 inches in diameter. The pieces to the right marked A were used as flue sheets and the outside cut was the only one made. Eighty-five 1½ inch flues were gas welded. The specifications called for steel castings and when it was found that no machining was necessary after being cut it was found that we could make these flanges and flue sheets much more economically and quickly than the foundries could. This also eliminated all question of porosity so common with steel castings. The speed of cutting was 6 inches per minute. When cutting circles with the radiagraph the inside tractor wheel is removed and a screw pivot is set on radius rod, the point of the pivot resting in a center punch mark. If a larger circle is to be cut the small radius rod can be removed and a larger one set in. Circles of any diameter can then be cut. You will also note that the trailer wheel is set to the radius of the circle.

The impression, due to printed reports, that steel cutting with the oxy-acetylene process could not be carried on above 10 inches in thickness, is surely all wrong, and we submit a picture (Fig. 3) of two mighty fine specimens of steel billet cutting 14¼ inches square, carbon content .30, that was cut with oxy-acetylene. The time for cutting was 6½ minutes per cut and oxygen consumption 100 cu. ft. You will particularly note how smooth, straight and clean each cutting surface is, and also the lack of oxide on the bottom of the cut. This certainly proves that steel cutting over 10 inches can be accomplished, with the above mentioned process.

While on the subject of heavy cutting, the writer witnessed a feat of handcutting sometime ago that we believe is the most remarkable on record. The cutting was done on 55 inch hexagonal ingots. The operator used a No. 10 tip and 195 lbs. of oxygen pressure, 7 lbs. acetylene pressure. Starting at the end of ingot the operator carried his cut along until he was cutting 37 inches clear through from top to bottom when a pocket formed on the bottom of the ingot and he was forced to stop. He then started on the opposite side of ingot and carried his cut through until he was cutting 33 inches clear through from top to bottom. The ingot was then broken by dropping a 5 ton ball on it. These measurements were then confirmed. There were four of these ingots to be cut and this operator did the same kind of cutting on the three that he did on the first one.

Figures No. 4 and No. 5 show some



This material was prepared by the author, who is engineer of Airco-Davis-Bournonville Co., for the American Welding Society. The first part appeared in June 29 issue.

of the most remarkable radiagraph cutting ever accomplished in this country. The parts cut were harveyized steel plate. The drawings and specifications called for a thickness of plate of .375 of an inch, 169.30 inches long and 89.78 inches wide, and were used for top and bottom plates for gun carriages supporting a 9 in. gun. No. 5, the top plate, shows center that was cut out. also a circle 12.602 inches in diameter cut out. It will be noted that the right side of this center piece is cut to a radius of 90.03 inches, also the bottom of right end is cut to a radius of 9122 inches. The balance of center piece is straight cutting. To accomplish this cutting it was necessary to make cuts very accurate and straight (down) as we were only allowed .015 of an inch either way because machining after cutting was not figured on. In fact, we were told that if our machines could not cut that close to line, they would have to look further for other methods. Special tracks were constructed and bent to the same radius as the cut to be made for the three uneven sides and straight tracks used for the one straight cut for both top and bottom plates. After the tracks were bent, they were bolted in place, and cutting started. After completion of cuts the plates were allowed to cool, when they were checked up by government engineers, and then O. K.'d. Four radiagraphs were used on this work, covering a period of close to eight months, these machines being in operation continually. All other opening in plates shown in photos were cut with the oxy-acetylene process. Anyone familiar with government requirements on this class of work will readily appreciate the most remarkable performance of these machines. To the casual observer watching this cutting being done, it appeared to be a very simple matter, but to those of us who had worked on this problem for weeks, it was anything but simple. Two

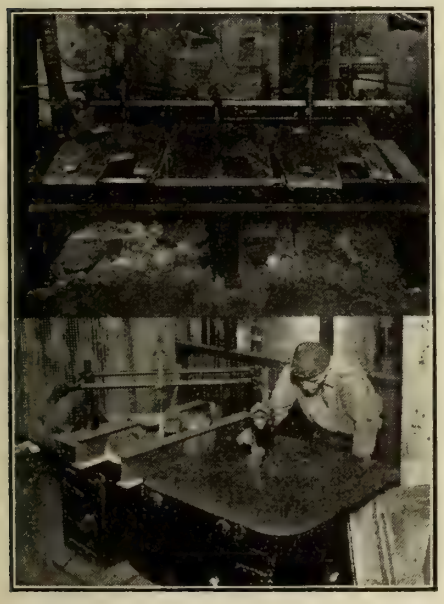


Fig. 12.—Top: Cutting two plates at once.

Fig. 10.—Lower: Tracing made directly on table top.

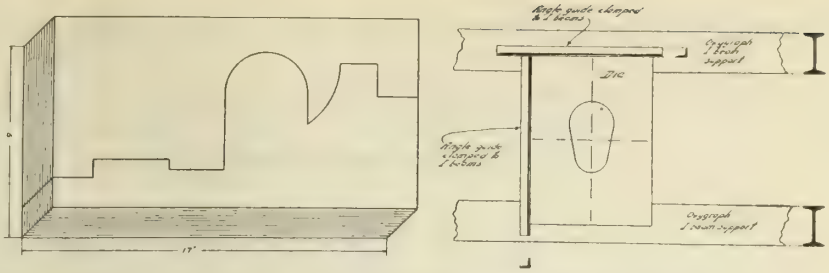

Fig. 11.—Only bottom plate required machining after cut was made.
Fig. 9.—Method of holding dies to be cut with oxygraph.

of our troubles bear mentioning here. When the tracks were built, and sample cuts were made on ordinary plate, it was found when checking up our openings that the radius on top and bottom did not conform to the radius of track, and radius of drawing, and after quite a bit of study we remedied this by moving the torch over to the center of machine so that it was directly in the middle of tractor wheel in front, and trailer wheel in back. Then our cuts come out strictly to line. When the first harveyized plate was cut, it was found, to our surprise, that the cut was very ragged and rough. Then it was found that we were cutting on the harveyized side so then we turned the next plate over and cut on opposite side.

The writer previously mentioned that the radiagraph was primarily built for straight line and circular cutting, but with a little ingenuity could be set up to cut squares, ovals and long irregular cuts. To make an irregular cut, a template can be made the same shape as the piece to be cut, and set on top of plate. The arm torch is then allowed to swing free, and tip is held close to template with a spring. In doing this there is hardly any limit to the shape of piece you wish to cut. In cutting ovals and squares the machine travels a complete circle while the spring holds the torch tip to the template.

In one of the largest mills in the central west engineers were confronted with a proposition that called for a cut to be made on ½ inch steel plates. These plates were approximately 8 ft. wide by 30 ft. long, as per Figure 6. This cut was 12 ft. in length and of sixteen different radii. After cutting they had to fit accurately other pieces for forms. Hand cutting was figured on, and it was found that too much chipping and grinding was necessary in addition; also to continue hand cutting involved the purchase of at least ten new hand cutting equipments. The engineers turned their attention to machine cutting and purchased a radiagraph. A template was then made like the cut to be made, with the various radii, out of ⅛ inch black iron, 15 inches wide. A special torch was then built, which swung freely on the post of the machine, and a spring attached to post and torch to keep torch against template, so that while the radiagraph would run on a straight track the spring would hold the torch to the template, making this cut exactly as laid out on blue prints.

In cutting one plate at a time, the set speed was 22 inches per minute and it was found that this was too slow, as these plates were to be delivered at a certain time that was fast drawing near. Four plates were then stacked up and cut one at a time. Eight plates were next stacked up, one on top of another, and cut at one time. These two cuts were so successfully made that it was decided to cut twelve plates simultaneously. After these plates were set up a bolt was set every three feet to hold plates as close together as possible. The speed of the radiagraph was set at 12 inches per minute. Thus the cutting speed on the single ½ inch plate was 144 inches per minute or 720 feet per hour. The cut was so successfully made as to speed, smoothness, straight vertically and so clean and to the line, that they were ready to be installed without any further labor. The balance of the plates were cut as described. To the writer's knowledge, this is the first time so many feet of half inch plate have been cut by a single cutting torch in one hour.

At this same plant, large steel slabs 31 inches and 11 inches thick were being cut by oxy-acetlyene, as shown in Fig. 7. This operation consisted of rounding off both ends and was being done with a hand operated machine, the torch moving up and down by a work screw and moved in and out to conform to radius on a bracket; one man operated a hand wheel on a screw to move torch in and out, while a third man held and moved hose in and out as the torch moved. The length of this cut was 44 inches and time consumed in making this cut by hand operated machine was 21 minutes. This cutting was a great deal more economical than free hand cutting, and smoother, but they found it did not eliminate the machine work that was necessary after cutting.

This operation required the service of three men to make a cut. The writer questioned the necessity of a man to hold the hose, and it was explained that this was necessary, as it was impossible for the second man to move in or out when the hose was lying down, as the weight of the hose would bind torch on bracket. The radiagraph was then used on this cutting, and not only did the cutting in 11½ minutes, but cut the gas consumption in half, requiring the services of but one man.

(To be continued)

Causes of Warping in Heating and Cooling of Ste

Problem One of Vital Importance—General Theory That of Changes in Volume—Furnace Conditions Should Be Carefully Watched—Experiments Disclose Interesting Results

IN REPLY to the question: "What are the causes of warping in the heating and cooling of steel?" submitted to the membership of the American Society for Steel Treating, the following statement was given by Stanley A. Richardson, instructor in metallurgy, Lewis Institute, Chicago:

The warping of steel has been a problem to steel treaters, it may be said, since steel treating began. With the increasing use of heat treated structural parts, particularly those of considerable length or cross section, the problem has increased in importance. It is held quite generally among shopmen that warping is in some way the result of nonuniform heating or cooling. Cracking, during or subsequent to heat treating, is thought to be due largely to the same thing. That is to say, warping and cracking are phenomena of like kind, differing only in degree. It is probably correct to say that the majority of technical men attribute these phenomena to the volume changes associated with the passage of a piece of steel through critical temperatures.

It is evident that the aforementioned views are not antagonistic, but are substantially in agreement. If a volume change causes a piece of steel to warp or crack, it must be because there is an interval between the time of the change in various parts of the piece, and this of course means that the rate of cooling, or heating, is not uniform. It is undoubtedly true, however, that there are many heat treaters who overlook the fact that a piece of steel undergoes a sudden expansion while cooling through the critical temperature, or, the reverse on heating.

In addition to the above, it is sometimes held that warping is due to a mechanical action, wherein the section of the steel cooled at the more rapid rate "upsets" the section cooling, at the slower rate. In view of the fact that in a piece of steel, one side of which is quenched in water, the quenched side is found to be longer than the side cooling in air, it is not clear to the writer just how this "upsetting" can take place. It is conceivable, and a matter of fairly common observation that steel can be warped by uneven heating before reaching the critical temperature. Such a condition is due, evidently, to the fact that because of differences in the rate of expansion of adjoining sections, stresses are set up which exceed the elastic limit of the steel and thereby produce distortion. Assuming homogeneous material, proper furnace design and proper furnace loading, should greatly reduce, if not eliminate this condition. Warping of this nature is probably more noticeable in the case of pieces of great length or uneven cross section. The tendency of steel to warp or crack under this condition is said to vary inversely with its thermal conductivity and directly with its coefficient of expansion. It is more pronounced, of course, in some steels than in others, probably reaching a maximum in high manganese steel, which can be cracked very easily by uneven heating.

The writer has listened to much discussion by practical men relative to the foregoing. However, after examining a number of the specimens presented, he is of the opinion that the real mechanism of warping in steels quenched from above the critical range, in the vast majority of instances at least, hinges upon the formation in the steel of varying amounts of the constituents marking the transition from austenite to pearlite, for example, martensite, troostite, and sorbite. It is a matter of common knowledge among metallurgists that each of the metallographic constituents of steel possesses a different specific volume or density. Quantitative determinations confirming this have been made by various authorities, notably Maurer and other prominent European metallurgists and physicists. Martensite, the constituent produced by quenching a piece of properly heated steel in water, has a greater specific volume than any of the other constituents. In a piece of steel, the greater dimension of which is length, this is equal to saying that the piece will be longer after quenching than before. Troostite and sorbite each have a specific volume somewhat less than that of martensite. When martensite and troostite, or troosto-sorbite are formed in quantity in a piece of steel, the ideal condition for distortion exists. The effect increases with the increase in the carbon content, which means of course that the effect depends upon the total amount of martensite and troosto-sorbite present. A piece of low carbon steel containing these constituents will undergo a slight deformation, whereas in a high carbon steel the deformation will be quite pronounced, or, in most cases due to its low ductility, the steel will crack. The cracks are usually parallel to, and close to the line dividing the martensite from the troostite, and appear to be due to the tension placed on the martensitic area by the contraction accompanying the formation of troostite. Frequently in a high carbon steel, cracks appear also in the martensitic area in a direction at right angles to the previously mentioned dividing line. The tendency to crack is influenced profoundly of course, by the degree of temperature to which the steel is heated above the critical point, being greater in steel highly overheated. That is to say, coarse grained martensite is more brittle than that of normal grain size. The production of concentrated areas of martensite and troostite in a piece of steel may be caused by uneven quenching or cooling of the piece, unequal temperature throughout at time of quenching, unequal drawing or tempering, and probably, nonuniform distribution, or concentration of the elements, particularly carbon. The last mentioned condition can usually be corrected by a thorough anneal, while the others depend upon factors peculiar to any individual plant.

The following simple experiments, performed in studying this problem, are interesting, and can be duplicated in any shop. They were carried out under shop conditions without attempt to exact quantitative data. The changes in dimension were measured chiefly by tracing the outlines of the pieces on paper before and after the heat treating operations. Pieces of 0.20 per cent carbon, 0.50 per cent. carbon, and 0.90 per cent. carbon steel each about 6 by 3 by 3-8 inches were heated to their respective proper quenching temperature and quenched about one-half of their width, that is about 1 1-2 inches in cold water, and the microconstituents noted. In addition, pieces of 0.50 per cent. and 0.90 per cent. carbon steel were heated and quenched uniformly, and then immersed for about one-half their width in cold running water and a drawing temperature applied to the upper edges with an acetylene torch. This temperature probably reached 900 deg. Fahr. at the upper edge of the piece and graduated downward to the surface of the water. The results obtained including the cracking were almost identical with those obtained by quenching but one-half of the specimens in water and not tempering.

In the case of 0.20 per cent. carbon steel it is necessary to quench the piece at least twice in exactly the same manner to produce a very marked deformation. This is to be expected when it is considered that steel of this carbon content can possess but 24 per cent. of saturated martensite. As the stresses set up by each quenching exceed the elastic limit of the steel, the effect, that is the distortion, is cumulative. If the piece is very wide a bulge will be noticed on the ends of the section farthest from the surface of the water, for example, the section cooling at the slowest rate. This bulge will have a greater length than the troosto-sorbitic area, but less than the quenched or martensitic area. Upon examination it will be found to consist of lamellar pearlite.

The only opportunity some people ever hear calling is the whistle at five o'clock.

Practical Ideas From Practical Men

INDEX STOP PIN FOR DIES

By I. N. B.

Sometimes it is difficult to use a pilot in locating a previously punched hole in blanking dies. The sketch herewith shows how this was accomplished in making the price shown in Fig. 1. The slot had to be in the vertical centre of the blank and 20 deg. off the bottom circular part. Fig. 2 is a top view of the die. The punch was fitted with a spring stripper which held the stock flat and did not distort it when the punch left it. The slot was punched first, at the same time the indexing punch cut a notch in the edge of the stock. The toe latch, located at the proper spacing distance engaged the notch and at the same time pressed it against the guide pins on the second stroke of the press when the piece is blanked out.

As the notching punch is opposite the guide pin it has the same bearing point when shifted to where the toe latch engages it, hence the slot comes in the proper position in the blank when the blanking punch removes it from the stock. If the slot was punched out after the piece was blanked out it would have a tendency to distort the ends. It will be noticed that the slotting punch is set at an angle of 5 deg. This is done so as to get the blank out of the narrowest width of stock possible. The toe latch is pivoted on a shoulder screw resting against a spring push pin. On feeding the stock forward the latch will ride on the edge of the metal at the same time holding it against the guide pins until the notch is engaged, when the push pins will cause the stock to move back and the opposite side of the toe latch lever will strike the adjustable set screw and the next stroke of the press will punch the blank. As the guide pins and the end of the latch is hardened and the bearing point is small there is not much pressure on the stock, and as the dies are unobstructed the operator has full view of the work to aid his sense of feel in handling the stock on work where the spacing is short. The foot can be kept on the treadle of the press for runs of a minute or more, thereby getting the full capacity of the press. The sketch shown is as used on a spring stripper punch but can be used with a fixed stripper on the die.

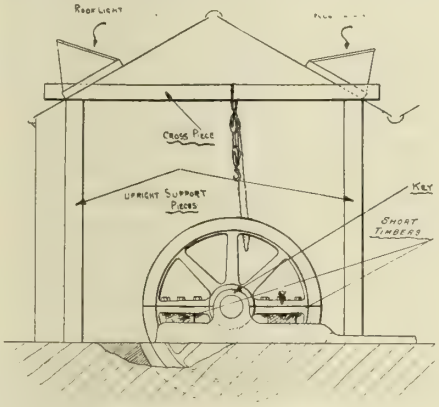
LIFTING AN 8 TON FLYWHEEL

By G. Blake

Some years ago while the writer was works engineer in a factory, we had a rather awkward job. The 8 ton flywheel on the engine became loose on the shaft; this flywheel was in halves and held together by bolts. The flywheel was held in position by one key and it was this key that caused the trouble, with the constant thrust on the one side it gradually began to wear (on the thrust side) slowly at first, then more rapidly until it became quite slack; fortunately it could not get out as there were bearings on either side of the boss of the flywheel. However, the key became so loose that it was decided to fit a new one. As already mentioned the flywheel was in halves, the difficulty lay in raising the half in which the key was fitted. Referring to sketch Fig. 2 it will be seen that the bottom half was supported by means of short stout pieces of timber, across the wheel pit, the timbers taking the weight of the bottom half when the nuts were slacked off. How we raised the top half of the flywheel is as follows; there was no overhead crane in the engine house, which by the way was of light construction. The two roof lights which were directly over the flywheel were utilized, a stout heavy baulk of timber was fixed up in position through the roof lights (see sketch Fig. 2) and was supported by two similar baulks of timber, one at either end, as near as convenient to the flywheel, the two uprights taking the weight while the roof lights prevented any side movement. A 5-ton chain block was slung to the cross beam. The rest of the story needs very little telling as the sketch Fig. 2 explains it clearly. The new key which by the way was prepared before hand, did not take long to fit and the engine was soon running again.



Lifting an 8-ton Flywheel.

HOW TO SPEND LESS FOR COAL

By W. F. Schaphorst

When coal is shoveled into a furnace, where does it stop? On the grates, of course. Are those grates efficient? Are they designed for the most economical combustion of coal? Are you needlessly burning money on your grates? These questions certainly should not be rudely brushed aside. Grates are worth thinking about because they may be either highly efficient or extravagantly wasteful. That's where you put the coal, in the very first step towards converting it into mechanical energy. That's where it lies through the whole combustion process. We do not take it from

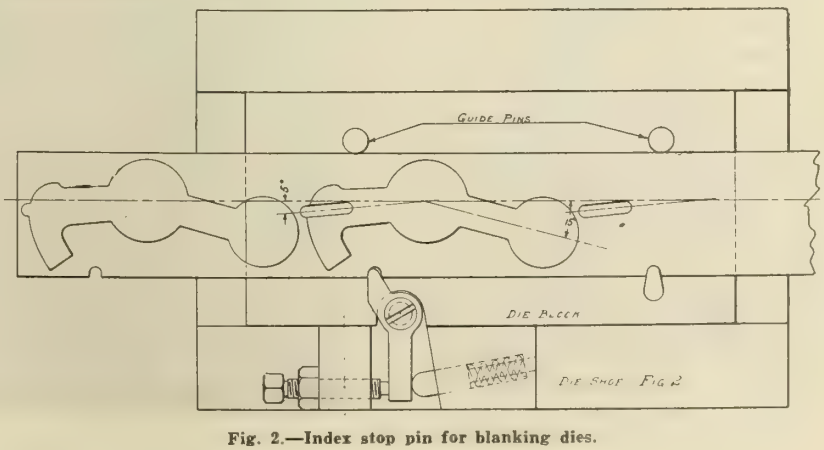


Fig. 2.—Index stop pin for blanking dies.

the grates and put it somewhere else, as we do other materials in turning out products—it "lives" for a few brief moments on the grate, gives a small part of its life to doing useful work, and also gives a greater share to wastefully heating exhaust steam or atmosphere. After death its remains drop through the grate in the form of ash.

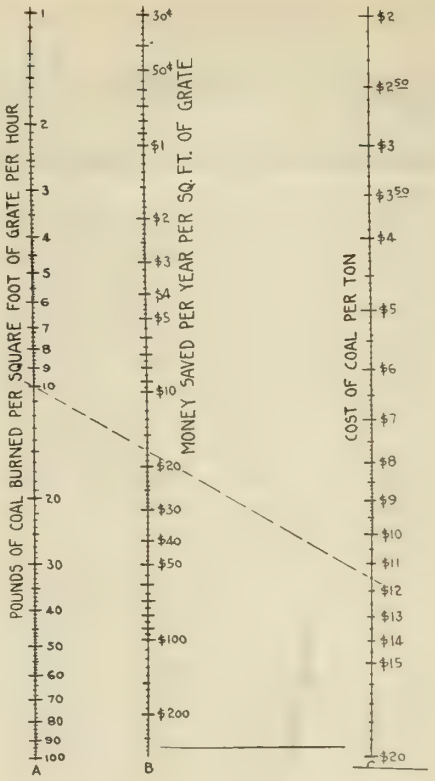
It is therefore plain that the grate has very much to do with the combustion of the coal. That is the place where economy must be effected first of all. I don't know why it is that the grate has practically been ignored by engineers in their efforts for economy in the power plant. It has been pointed out time and again that engineers delight in perfecting engines, turbines, steam lines, condensers, economizers, feed water heaters, and the like, but they keep away from the grate—perhaps because grates are usually so black and dirty. In the process of combustion one can't see any "wheels go round" and mechanical geniuses evidently lose interest.

Every little leak, however, is worth plugging nowadays, and as there are so many big leaks in furnace operation I will dwell on the subject for a moment longer. I have some figures here that should prove of interest.

In a letter from a prominent grate manufacturer he says, "grates will show a saving in fuel of at least 10 per cent. over ordinary plain grates in any case. It has gone as high as 20 per cent. We are willing to guarantee a 10 per cent. saving over plain grates." This statement alone gives us enough data on which to work. What was your coal bill last year? Are you using plain grates? If so, take 10 per cent. of your last year's bill and put most of it in the bank this year by improving conditions. Or, on account of the present high cost of coal perhaps you can "come out even" this year at least.

Getting down to a concrete problem let us say that your plant is a place where coal costs from $11.50 to $14 per ton. Let us assume that you run your plant 10 hours per day, and 300 working days per year, or 3,000 hours; assume that you burn 10 pounds of coal on your grate per square foot every hour; and lastly assume that the most economical form of grate can be purchased for $5.50 per square foot. How much money would be saved per square foot per year?

There is nothing difficult about the problem. You will readily figure that 3,000 pounds of coal are burned on a square foot per year. If 10 per cent. of this can be saved by installing better grates it is plain that 3,000 pounds of coal would be saved per square foot per year. At $11.50 per ton this amounts to $17.25 per year. That will be the saving at the end of the first year, but it is not the net saving. From it we must subtract $5.50, the cost of the grates, which leaves $11.75 as the saving. Thus you could instal new grates every year and still make good money. If your grate money is 100 square feet



you will multiply this by $11.75 to find the total net saving, or $1,175 per year.

To make the computing work still simpler, I have developed the accompanying chart. Simply lay a straightedge across the chart connecting the pounds of coal burned per square foot per hour (column A) with the "cost of coal per ton" (column C) and the intersection with column B immediately gives the saving on expenditures for coal per square foot of grate area per year. From this subtract the price you will have to pay for a square foot of grate and you can decide for yourself whether or not it will pay to make any change. The dotted line on this chart shows how the problem given above would be worked out via the straightedge. Column B shows the saving to be $17.25. Even if the saving were only 5 per cent. the investment would pay, but inasmuch as 10 per cent. is guaranteed I have based this chart on that figure.

EYELET SET

By J. H. W.

Herewith is a sketch of an eyelet set to be used when the material in the eyelet is of such a frail nature that it will buckle rather than turn over or roll, so to speak. The rounding section of the punch has a series of sharp chisel points which cut the metal so that it will turn over neatly.

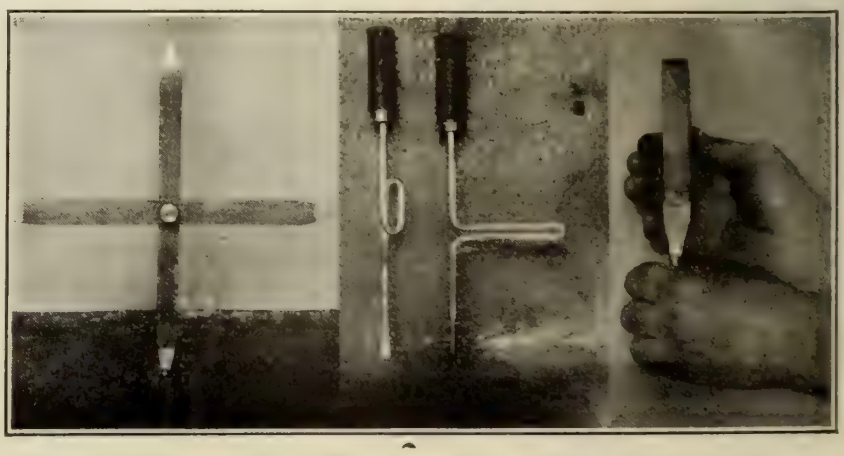
EXTRA LEVERAGE SCREW DRIVERS

By H. M.

The subject of extra leverage on screw drivers calls to mind the time honored monkey wrench, the application of which has long been familiar to the average machinist. There are numerous cases where the ordinary screw driver alone does not answer the purpose, and it is necessary to devise some means to procure a better purchase. While a monkey wrench or spanner may be utilized as an emergency tool, it must be admitted that the method is a clumsy one.

In the accompanying illustration are shown a few screw drivers equipped with means for additional leverage, and as these are seldom seen in general use they will likely be interesting to many readers. In the first view is shown a tool that will start any screw that is removable at all, and being constructed with four blades of different width and thickness, the right blade for the screw can always be used. One part of the tool is made of ⅝ x ¼ in. tool steel, the other of ½ x ¼ in. for the smaller screws. The two blades are held together by a knurled nut and bolt. It can be folded up and carried in a tool kit.

The second view shows two round shank screw drivers with a loop in the rod for leverage. These tools cannot be used in confined space as room is required for the loop to turn. A very handy driver can be made from old saw blades as shown at the right. One blade is bent double for the handle, care being taken to bring the holes in line. The blade of the driver is then made to the desired shape and riveted to the handle.



Several handy screw drivers.

New Things in Shop Equipment

INTERNAL GRINDING MACHINE

A new and highly efficient type of grinding machine of interesting design has recetly been developed and placed on the market. It is the invention of Fred E. Bright and is known as the Bright internal grinder. The new fundamental feature (patented in many coutries) is the revolving and reciprocating of the work carrying spindle in one bearing, eliminating the necessity for exact alignment of it with other essential parts of the machine. Due to this fact great accuracy and efficiency are possible in the finishing of straight round holes. The grinding wheel spindle is directly driven, so that slowing down due to belt slippage is avoided, and the wheel speed can be continuously and accurately maintained. Other features such as the simplicity of control and the accessibility of the work, are certainly worthy of note.

The wheel spindle driving motor is located at the top of the machine. The main motor for operating the work spindle and feed is placed at the back of the main frame. The machine is entirely self-contained and no belts or countershafts are required. The wheel spindle motor is of the induction type without brushes and operates at high speed. The outside diameter of the housing is only 5¾ in. and the motor generates 1½ h.p. Double-row ball bearings are provided for wheel spindle, one at top and bottom. Special extensions can be fitted to lower end of spindle to suit the various classes of work.

In order to change the speed of the wheel spindle, the frequency of the current driving the motor must be changed. The frequency-changing device ordinarily employed consists essentially of a variable speed d. c. motor driving an alternator. It is thus possible, by merely changing the resistance in the field circuit of the d.c. motor, to vary the number of cycles, and consequently the speed of the spindle motor. At 120 cycles, or the minimum speed, the spindle motor runs at 7,500 r.p.m.; at 200 cycles, the speed is 12,000 r.p.m., which is the maximum, these and intermediate speeds proving to be effective because of their maintenance at predetermined rate without slippage. Where a single grinding machine is used, a small frequency changing unit may be employed. Where a battery of the machines is operated, one installation may serve for the entire group.

The wheel spindle and its motor are mounted on a yoke that pivots about the supporting column. This column can be lifted by means of a lever at the right side of the machine, so that the wheel clears the work. After the wheel has been raised, the whole head can be swung to the left of the machine, so as to provide clearance for removal and replacement of the work, as shown in Fig. 2. The column consists of two telescoping parts, whose relative position is controlled by means of a screw operated by the handwheel at the top. It is thus possible to vary the length of the column, and, consequently, the height of the wheelhead.

The feed screw, which is mounted in the housing back of the wheel spindle, is provided with a large graduated wheel, that permits of a feed of 0.0001 in. per graduation. Automatic feed is made at each end of stroke. An automatic stop is provided for finished size. The wheel is dressed by means of a diamond fixed to the housing of the work-holding chuck. It is provided with screw adjustment as wheel wears down. The chuck or fixture holding the work is mounted at the top of a hardened steel spindle 3 in. in diameter and 20 in. long, that is carried in two phosphor-bronze bearings fixed in a housing that can be easily removed.

The wheel spindle is made of hardened steel, more as a protection when assembling than as a factor of wear, as the shaft runs continually in a film of oil and the pressure when grinding is so slight that the wear is almost nil.

The chief feature of the machine is that the spindle both rotates and reciprocates in the same bearing. Consequently, the work reciprocates in the same line about which it rotates. Since the wheel maintains one position only, a straight and round bore must result. The weight of the spindle and work is carried on one ¾-in. ball at the bottom.

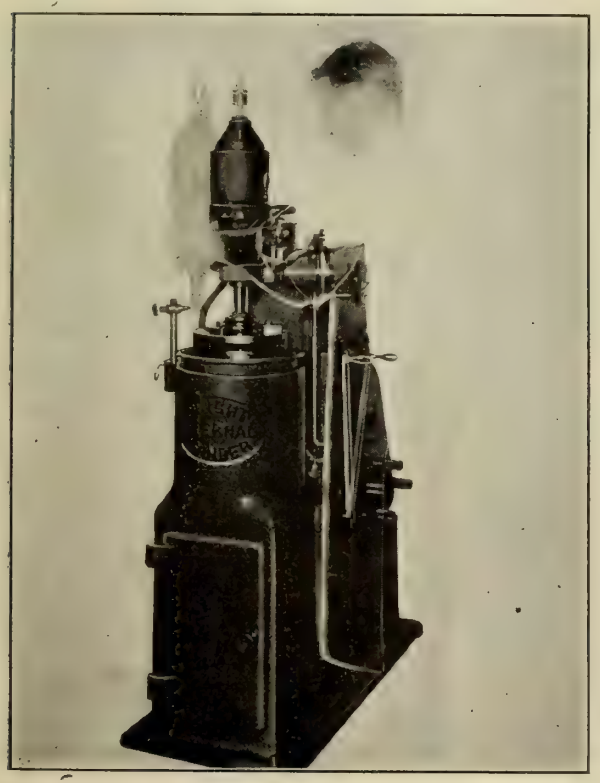


Fig. 2.—Convenient method of swinging spindle clear of work.

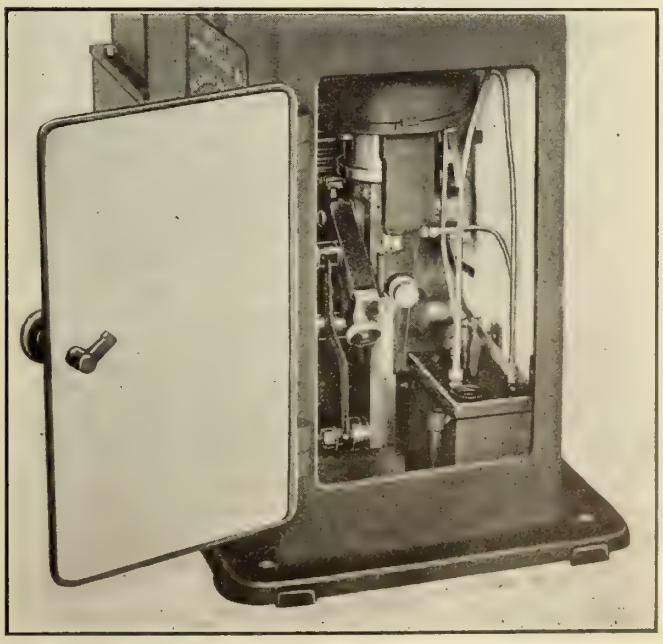

Fig. 3.—Interior view of base, showing work spindle mechanism.

This ball rests in a small pocket that allows sufficient clearance for it to travel eccentrically about the centre line of the spindle, so that it wears uniformly. Removable hardened steel disks are provided both above and below the ball.

The spindle is driven by means of three flexible steel keys, mounted in a bevel gear running on a separate bearing with clearance around the lower end of the spindle. As the spindle reciprocates, these keys slide in vertical splines. The bevel gear is mounted on ball bearings and is driven by a pinion carried on a shaft, also running in ball bearings, and connected directly to the speed-change gear box at the rear of the machine. The work spindle is lubricated by force feed from the small pump, Fig. 3, placed in the front of the base and driven by the stroke mechanism.

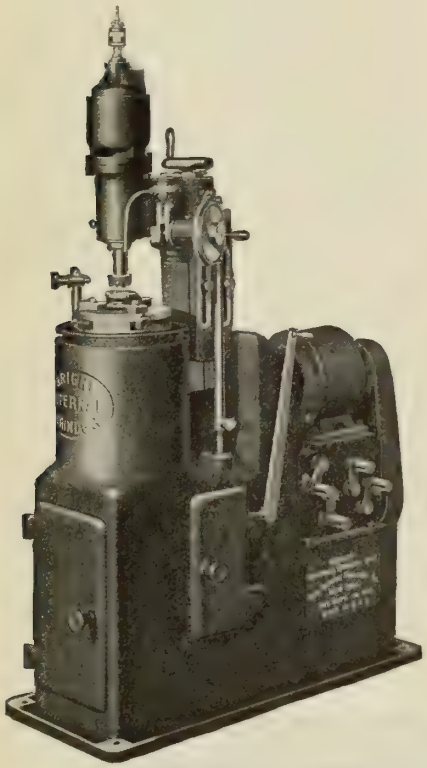

Fig. 1.—Bright internal grinder.

The oil is driven to the top of the top bearing, and works down through the two bearings to the bottom of the spindle, where it drops off into a small cup, from which it is led back to the tank of the oil pump. Some of the oil is diverted to the bevel gears, so that both they and their bearings run in oil. The oscillating action of the work spindle is obtained from a separate shaft driving a cam through worm gearing. The cam is designed to give a uniform motion to the spindle, although a variable speed can be obtained by applying suitable cams. The stroke is regulated by means of a small knurled screw. The spindle rotates at a speed of from 100 to 385 r.p.m., the reciprocating speeds varying from 4 to 48 strokes per min. These Bright grinders are made by the Garvin Machine Co., New York.

HORIZONTAL STAY-BOLT MACHINES

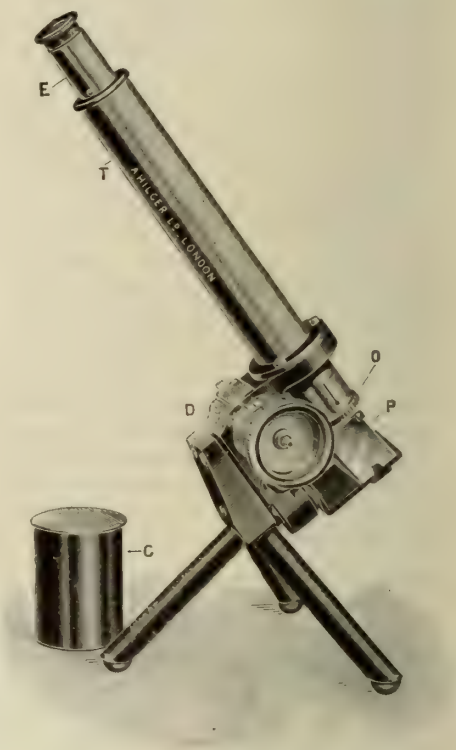
There has recently been placed on the market two horizontal stay-bolt machines adapted for turning simultaneously the taper and straight diameters on radial, button-head and crownstay bolt forgings, and for threading both straight and taper ends. Collet bushings and adjustable straps are provided for turnings. The front-head has a taper attachment which can be adjusted to any desired taper. The rear die-head cutters are straight while those at the front heat are tapered. Both die heads are automatically operated. The machine may be adjusted to any desired length by means of a permanent spacer bar. This bar having twenty-three holes accurately bored and spaced to correspond with the various lengths of bolts. The machine has a capacity of bolts 1½in. in dia. up to 36in. in length. The style A machine is designed for making stay bolts from the bar of either iron or copper. The cutting and threading tools are held in a turret which slides directly on the ways of the machine. The bar stop is automatically fed through the spindle of the machine. When threading the bolt special provision is made for advancing the dies quickly over the relieved portion with the lead screw still engaged. Both styles of machines are fitted with automatic tripping devices for turning and threading. Safety devices are provided so that no two feeds can be engaged at the same time. These machines are manufactured by the Millholland Machine Co., Indianapolis, Ind., and are known as the style A and style B Lassiter-Millholland sty-bolt machines.

CHEMICAL SPECTROMETER

A novel design of spectrometer has recently been developed. It is similar in appearance and size to a microscope, and takes no more room on the table. The telescope (T) has in its eyepiece a slit and small autocollimating prism for introducing the light. After passing through the object glass (O), the rays of light proceed to the 30° prism (P). This prism is silvered on the back surface, and the light then retraces its path through the object glass (O) to the eyepiece by means of which the spectrum is viewed. The prism (P) is mounted on a table provided with a lever, and is rotated by means of a micrometer screw pressing against the lever, to which screw is attached a drum, on which is engraved the scale of wavelengths. The index moves along a helical slot. An enlarged view of the drum is shown herewith. A cover (C) is provided for the prism for protection and to exclude extraneous light other than that from the slit; and a small mirror with clamp for attaching to the telescope is also provided (not shown in the illustration).

The instrument is supplied in wooden case with carrying handle, the outside dimensions of the case being 9½″ x 8″ x 16½″ (24 x 20 x 41 cm.) high. Thus it is very compact for storing and convenient for transport. Being self-contained the instrument may be quickly moved from the case with one hand, and is then ready for use.

A number of accessories are used with the instrument. For investigation of arc spectra an arc taking about 2½ amps. is quite sufficient. This will work well on any ordinary lighting circuit. A rough stand capable of carrying this can easily be made where saving of expense is imperative, and this with a resistance which may conveniently



Chemical Spectrometer

ly take the form of a board with a few carbon filament lamps connected in parallel, provides all that is necessary for the most accurate work.

It is manufactured by Adam Hilger Optical Works, 75A Camden Rd., London, Eng.

BOOKLET

The Electric Furnace Construction Co., Philadelphia, Pa., have recently issued new catalogues on their electric furnaces for melting, refining and superheating of iron and steel. This booklet illustrates the construction and operating features of their different furnaces. A booklet has likewise been issued covering the line of "Electro" steam boiler manufactured by them.

Adequate Machinery Building

RECEIVING the support to which it is entitled, the movement to erect an engineering building on the grounds of Toronto Exhibition, should find it to be an easy matter to guarantee that it shall be self-supporting. This is the proposition behind all modern buildings erected there as representative of different Canadian industries. Old Machinery Hall has been long inadequate for its purpose. It is as far short of requirements in housing the best that manufacturers have to display, as a child's shoe would be for the foot of a lusty giant. In fact, accommodation has been so poor, that each year was conspicuous not for the number of firms represented as for the number of important enterprises that were noticeable by their absence. The new building, as proposed, will be a credit to Canadian industry from every point of view, will emphasize national ambition in the engineering field, and serve to advertise to advantage the utility of the product for purposes intended. Already much has been done in segregating industries in proper buildings, and the successful scale on which plans have materialized is, of course, as highly creditable to the enterprise of manufacturers interested, as it is to the aspirations of the Exhibition directorate. If the project is received in the proper spirit the new building will probably be ready for 1923.

Encourage Blast Furnace Industry

BETTER DAYS would seem to be in store for the Canadian steel and iron industry as a native proposition, judging from the enthusiasm and the practical discussion of interesting facts at the meeting held before the Minister of Mines for Ontario a few days ago. It was attended by metallurgists, mining and furnace men who have been closely identified with the industry up to the present time. If any apologist were needed for such a meeting, his chief duty would apply to the lack of encouragement that has been accorded an industry which, according to authentic report, is in every sense indigenous. It was established that Canadian ores, as produced, were the equal of anything on the market, both chemically and physically. This was the statement applied to the mine at Moose Mountain, where magnetite ores are briquetted, while as regards the investigations conducted by the Algoma Steel Corporation it was pointed out that by a mixture of Canadian siderites and magnetites, an ore could be produced cheaper by $1.57 than anything offered by American mines in a similar grade.

The problem is one that hinges on Government assistance to bridge the gap as between mines and blast furnaces, and organization by which the requirements of the market might be served by Canadians as it is now served by Americans. Opinion seems to be pretty much in favor of a bounty, say of 75 cents at the mine's mouth, but as an alternative proposition there seems to be something worth considering in the possibilities of electric power at a nominal figure. Such a plan seems to have been instrumental in developing the industry in Sweden, where power is available at a very low rate.

As confined to Ontario alone, there are frequent vast deposits of magnetic ores from the Ottawa region on the east, to the Superior region on the north, with here and there deposits of natural ore, but not in sufficient quantity to warrant commercial venture. In the Hudson's Bay region there are said to be ranges of the same character as that in Newfoundland, but while there seems to be fairly accurate knowledge as to available ranges, there has been no exploration or investigation as to concentrations at depth. Such work is essential for there seems to be no problem in connection with Canadian ranges that has not existed with developments in the American industry.

Canadian blast furnaces are willing to deal with producers, all things being equal in the matter of price and chemical analysis. There is a growing feeling that here is an opportunity for Canadians to develop an independent industry in the interests of the country, and that there should be no "laying away" of ranges in behalf of foreign interests.

Good Business in Mining Region

AS A SOURCE of good business for the steel and iron industry, and in that we include machinery manufacturers and foundry operators, the northern mines of Ontario are developing an importance that commands consideration. Not infrequently it occurs that demand from this quarter has helped to tide over many an enterprise which, confined to its usual field, might have found a lapse of operations necessary. The production of steeel and iron crusher balls for use in ore grinding has alone helped the foundry industry, and in the same connection there has been a steady call for parts and repairs. For example, it is estimated that the amount spent in 1920 for ball mill liner, castings and machine shop work was about four million dollars; for chemicals and apparatus, about three millions; for drill steel, more than half a million, and almost a similar amount for electrical supplies. Machine drills and parts called for an expenditure of $692,174. The gross wages paid by the industry in the year referred to amounted to $25,764,461. Mining operations two years ago were considered in their infancy. New mines are being opened up, plants extended and new equipment installed. As the riches of the North are continually revealed, the products of industry are going to find an increasingly profitable market. The mining region is worth watching in the interests of good business.

Steel Industry Flourishes Despite Coal Strike

Blast Furnace and Steel Mill Operations Grow—Wide Spread of Industries Represented by Canadian Demand—Prices Remaining Firm—Demand for Sheets Strong Factor—Sellers Predict Good Business Next Autumn

SOME JOBBERS REPORT AN EXCEPTIONAL JULY

IN spite of the coal strike, it is a remarkable fact that the rate of pig iron production as reported from Pittsburg has increased 20 %, and that additional furnaces have been blown in recently. In short, there seems to be no menace for the future, as far as the steel industry is concerned. Mills are filled with actual business for approximately two months, and are not forcing any tendency of the market to contract for Autumn supplies. The activity in all grades of sheets may be judged from the fact that leading interests are filled for three months. Some of the independents have retreated from advances over regular figures.

From a buyer's point of view, the hope is expressed that conditions as reported in the steel industry, will continue after the vacation period, while among sellers there are predictions that buying will resume just where it left off. The market may be said to present a moderate aspect with reference to the price situation. Basis prices seem to be firmly maintained.

So far as Canadian industry is represented in demands for iron and steel, there is quite a wide spread; that this, no concentration on any particular line of activity. Thus, a representative in close touch with the field, reports that the past two week's tonnages contracted for were made up of structural steel, rim material for the motor car industry, bar products for agricultural implements and considerable transmission material, or cold rolled steel. There is no doubt that the motor car industry is responsible for an increasing amount of business that is of direct interest not only to iron and steel men, but also to machinery manufacturers. The official report that the Ford Company of Canada is preparing to spend millions in new buildings at Ford, Ont., not only to handle increasing export business to evidently to entrench themselves still more strongly in the Canadian market, is warmly welcomed by the machinery industry.

Prices for the most part remain steady, though there is an undertone of firmness reflecting good general demand and tendency created by coal strike problems.

Montreal reports that iron and steel business for July indicates a better demand than has existed for any ten-day period this year. In fact, some jobbers declare that July will be the best month of the year. This is significant, for generally the month is one of the most indifferent of the year. The demand for sheets, black, blue annealed and galvanized is said to be far beyond visible supplies. Structural steel is also becoming increasingly scarce and deliveries to replenish stocks are stiffening up. Here again appears a policy of cautious selling on the part of the mills. The market for pig iron is strong and foundries are showing an inclination to cover for future. Summerlee Scotch iron is making its appearance on the Montreal market at $29.75 dock, as against Canadian $31.80 track. A good volume of business is developing in machine shop supplies.

Toronto

July 12, 1922

HAVING reached the stage where there is a fairly strong demand considering that it is now the middle of July with the supply in fair quantity so far as iron and steel is concerned, the Toronto market, in some respects, is quite keen. The indifference of a few weeks ago with reference to the coal situation seems to be disappearing as the result of reports that one month hence may see a more serious situation. Practically no anthracite is coming into Toronto. Some bituminous is moving, from independent sources, though not in anything like regular quantities. There are said to be fair supplies on hand and one even hears of a tendency to consider lower prices as a possibility, but this is probably confined to the more optimistic. Be these things as they may, there is an element of activity throughout the market and while it cannot be said that there are any price changes to speak of, still the undertone is decidedly firm.

Shipments from Pittsburg and vicinity are beginning to show some improvement in the American freight rates. Thus, the car load price from Pittsburg prior to July 1st was 38 cents; to-day it is 34, while the l. c. l. rate is 48 1/2; Montreal rates that were 58 and 73, are now 52 and 65 1/2; St. John, N. B. rates were 84 1/2 and 106 1/2 are now 76 and 96; Halifax rates were 86 and 108, now 77 1/2 and 97; Guelph and London rates were 38 and 54, are now 34 and 48 1/2; Windsor, formerly 35 and 50 1/2, now 31 1/2 and 45 1/2. The present Kingston rate is 48 1/2 and 61. Further reduction becomes effective August 1, when the Canadian Railway Board prices apply.

Importations of steel during the past few weeks represent a wide industrial spread. The demand for structural steel seems to have a temporary easing, but there have been calls for rim steel for the auto industry; bar products for agricultural implements, besides considerable transmission or cold rolled steel. In contrast with the activity among the railroads in U. S. in renewing rolling stock and trackage there is very little doing in that line in Canada, outside of some good tonnages in rails.

The demand for sheets seems to be developing exceptional proportions reflecting the building activity in larger centres and also the increasing business in the motor car industry. The steel furniture industry is also well represented in this increase.

In scrap metals, there is no marked movement. The demand is moderate and there is not a great demand coming forward to the dealers. Large tonnages of steel rails, from the Toronto Transportation Commission, going to the Steel Company of Canada at $15.50, represent a clear run. The rails have to be free from all of the extraneous materials carried from the roadbeds from which they were removed. Price ranges are as follows:

Copper, light ... ... per 100 lbs.	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper Wire	11 00
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings ...	4 85
Light brass	3 50
Medium brass	4 50
Scrap zinc	4 00
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton ...	9 00
Heavy melting steel	11 00
Axles (wrought iron)	16 00
Rails (scrap)	11 00
Malleable	11 00
No. 1 machine cast iron	16 00
Pipe, wrought	6 00
Car wheel	16 00
Steel axles	15 00

Nor is there any marked activity in the so-called non-ferrous department. Prices show stability. It would seem that the market should reflect demand from the building industries but it is pointed out that in preparing for this overdue condition the brass founders producing plumbing fixtures,etc., were fairly well stocked and the material has to be absorbed. It is stated that last year one firm had as many as 16,000 bath tubs available against a building boom. This number of course means a corresponding supply of fixtures. Quotations are as follows:

Lake Copper	17 00
Electric Copper	16 75
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	6 75
Aluminum	26 00

The iron and steel bars, a solidifying movement is still in progress, though it as yet, seems to lack certain unanimity. It is a trend which is characteristic of the prevalent feeling that the time is approaching when there must be gen-

erally higher levels in the steel industry. However, there are those who incline to the feeling that improving conditions will eventually bring about a volume of business necessary to more profitable production. This they feel is the explanation, rather than very radical price changes. However, prices continue to show marked firmness:

Iron bars	2 90 to 3 15
Steel bars	2 90 to 3 15
Reinforcing bars	2,90 to 3 15
Steel hoops	4 00
Tire steel	3 15
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in base	3 50
Small shapes	3 15
Sheets, black, No. 28	5 00
Sheets, blue ann., No. 10	4 00
Canada plates, dull, 52 sheets	6 00
Canada plates, all bright	6 00
Galvanized Sheets, No. 28	6 00

In machine tools there is some movement, though hardly positive enough to warrant enthusiasm. Some machinery is being sold, and it is remarkable that inquiries are fairly good, but the orders actually closed represent a small proportion. The indifference of the holiday season is a factor just now.

Small tools and supplies are improving in general demand. Wholesale hardware houses state that there is not the demand they had hoped for in mechanics' tools. The opinion is expressed that there is here a problem such as exists in the machinery business—that used tools are too easily available.

Supplies for the building trades, such as valves and pipe fittings are said to be moving nicely. Though the demand is strong no advances have been made by pipe interests.

There is considerable strength in manufactured cottons. Wide ducks have advanced 2 1/2 per cent.

Montreal

July 12, 1922

A generally better tone reported last week in many lines is still being maintained, and the firmness in quotations is common to practically all metal products. July and August are generally conceded to be quiet months in iron and steel, but up to the present the volume in business in July has been heavier than in any ten-day period experienced this year. Jobbers even now state that July figures are away ahead of those of June and they confidently expect that July will be the best month of the year so far. The lines in demand this week are practically the same as those that have been active for the past few weeks. Black, blue annealed, and galvanized sheets are featuring the market. The supply of the latter has not been sufficient to take care of the demand for some weeks past. The call for structural sections, merchant bars, and small steel products is much better than it has been for some time past. Pig iron sales are slowly increasing. Machine tools, nonferrous metals and scrap materials are all rather quiet. General supplies and miscellaneous equipment are moving satisfactorily.

Iron and steel—All kinds of sheets are very active, with the demand for galvanized sheets far exceeding the supply. Prices remain steady as the competition is keen. Great regret is expressed by one jobber in galvanized sheets at the unfortunate collision of the tramp grain steamer "Airedale" and the Donaldson freighter, "Orthia." The latter was inbound with a large tonnage of galvanized sheets. Locally it is understood that these sheets will not be suitable for sales purposes. It is quite a calamity according to the jobber who claims to be consignee of the greater portion of these sheets. Quite a demand for structural steel in small and medium sized lots is present locally. Stocks are getting rather well picked over, and at present jobbers are looking for a source of replenishment. Early deliveries from the U. S. mills are out of the question at any reasonable figure. Merchant bar sales are gradually increasing. Plates are very quiet. The demand for steel products such as spikes, nuts, bolts and other small lines, is good. Miscellaneous lines such as reinforcing bars, steel hoops, tire steel, spring steel, etc., is very satisfactory. Prices remain firm at the increased quotations announced last week. Large consumers are able to obtain somewhat better prices, but there is very little evidence of slashing prices to any great extent. Competition is keen, but it is realized that business must be done at a profit and for that reason prices are fairly stable. Local quotations are the same as last week. The Montreal Tramways have been importing a considerable tonnage of the special grooved street railway rails from mills in the Chicago district. These rails have been coming down by water, largely as deck loads on the grain carriers. A considerable tonnage of billets have also been shipped from the Illinois Steel Works on these grain boats for use in the local rolling mills. This steel is largely unloaded at Lachine and the C. P. R. haul it to its destination. Local quotations are as follows:

Iron bars	3 15 to 3 25
Steel bars	3 15 to 3 25
Reinforcing bars	3 15 to 3 25
Steel hoops	4 00
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron.—Sales of pig iron have been very satisfactory the past week. The largest orders have been for Summerlee Scotch iron, which is being pushed at present. This iron is quoted at about a dollar a ton less than Canadian iron at points where water delivery can be made. Up to the present very little of this pig iron has been sold inland. At the same time the sales of Canadian iron are increasing. The improvement is gradual and as yet has not yet reached those proportions which would be stated as satisfactory. No changes in price have been made locally. The foundries that are in the market freely state that they are covering themselves for a period in the future, and that the iron purchased is not for immediate consumption. Reports show that the consumption in this vicinity is gradually increasing, but it is still a long way below normal. Summerlee iron is quoted at $29.75 on the docks and the Canadian iron is held at $31.80 on tracks.

Machine Tools.—There is no change in machine tools. Iron working tools are very quiet. An odd sale of a single machine tool is reported frequently, but in most cases the tools are small. Wood working tools are in a little better demand. The lumber industry is a little more active, as also is the furniture business. All business is keenly sought and prices are cut very close to get business.

Machine Shop Supplies.—Activities in the smaller shops are of such volume that these shops are constantly in the market for small tools and general supplies. The larger industries and the railways also contribute their share to the general volume of business. No orders are large but there are a large number of well scattered orders that make up quite a fair volume of business. Prices in most lines are fairly stable, and are reasonably low. Thus from week to week good business is reported from all jobbers. There have been but a few price changes for some time past.

Non-Ferrous Metals.— The local jobbers state that the amount of business moving in non-ferrous metals has varied but little in the last few weeks. No large orders have been received, the demand coming from all over the province for small lots. No price changes have been made during the week. The local quotations are as follows:—

Electric Copper	17 25
Castings, Copper	17 00
Tin	34 50
Lead	6 75
Spelter	7 75
Antimony	6 50
Aluminum	23 00

Scrap Materials.—The foundries have not come into the market for any scrap materials in the way that was expected, from the recent purchases of pig iron. The advancing price of steel had a tendency to make prices firm. The demand has not increased and the amount of sales for the past few weeks has been below expectations. There has been no change in the local quotations which are as follows:—

Copper, light per 100 lbs.	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper Wire	11 00
No. 1 compositon	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 00
Light brass	4 00
Medium brass	5 50
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton.	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	20 00
Pipe, wrought	7 00

Pittsburg

July 12, 1922

PRODUCTION of pig iron has been running at the rate of 30,000 000 tons a year since the first of this month,

against rates of 25,000,000 tons on April 1, and 19,300,000 tons at the beginning of the year.

Thus, during the first three months of the coal strike, the rate of pig iron production increased 20 per cent. and the furnaces are going strong, as production has been increasing continuously up to date. It is significant that additional furnaces have been blown in during the past two or three weeks. As it costs money to blow in a stack, this is rarely done unless a run of several months is assured, hence the evidence is that those who have lately blown in furnaces feel assured of a coke supply for an indefinite period. This means also that the attendant steel works are expected to have a supply of coal.

In other words, three months of the coal strike has allowed blast furnace and steel mill operations to grow and there is no menace for the future. If a shortage of coal is looked for the search must be made elsewhere than the steel industry. Thus far, moreover, consumers of steel have exhibited no signs of being short of coal or of curtailing their consumption of steel, for if they were in such a position they would be calling upon the mills to curtail shipments of steel to them, and nothing of this sort is occurring, buyers exhibiting as much desire for good deliveries on their recent orders as formerly.

The steel market has relapsed into dullness as it invariably does at this time of the year. There is some trading, particularly in tubular goods, sheets and wire products, but in general the market is dull. Mills assert that the dullness is attributable to their own position, in that they are unwilling to sell freely, and state that buyers would place contracts or shipping orders for later delivery if given the opportunity. There is some question about this however. Very likely many buyers would place blanket contracts if they could do so along the lines followed by the market before the war, when contracts were hardly more than options and when a buyer did not wish to accept deliveries he could avoid responsibility by refraining from placing specifications. As to actual orders, the probability is that consumers do not care to buy much more than they already definitely ordered.

The average manufacturing consumer has covered for steel against the orders he has actually in hand or in immediate prospects for his manufactured goods but he in turn must await the advent of autumn to see how business is going to turn out late in the year.

The steel mill position is a sound one, for the time being, in that all the mills are comfortably filled with actual business for approximately two months. In some lines, the obligations extend farther. In merchant bars, the mills appear well sold up through September. In sheets the leading interest is nearly filled for three months, while independents probably have an average of two-thirds of their prospective output sold to October 1. They could have sold more had they not quoted prices above the regular figures, adhered to by the leading interest. There has been a tendency among independents to recede from their position and quite a number are now quoting all grades of sheets except automobile sheets at the regular prices, 2.40c for blue annealed, 3.15c for black and 4.15c for galvanized. On early deliveries premium prices are frequently obtained, 2.50c; 3.30c and 4.30c respectively. In automobile sheets only the leading interest is quoting 4.50c, independents demanding and securing 4.75c or even 4.85c.

Wire Products.—Woven wire fence has been reduced 2 1/2 points or say $4 a net ton, and discount to consumers being increased from 68 to 70 1/2 per cent. and the discount to jobbers in carload lots from 70 to 72 1/2 per cent. Fence has been a very poor seller for a long time, and the formal reduction is probably due to there being more or less price cutting. On nails $2.40 remains the regular quotations of the leading interest while $2.50 continues to be the regular quotation of independents though it is admitted that $2.40 has to be accepted on orders for any considerable tonnage. Plain wire is quoted at 2.25c by all sellers.

For weeks, rods had been nominal at $38 and it was a question what would really be done on a forced purchase. A regular price of $40 has now been named by the leading interest.

Bars, shapes and plates, remain quotable at 1.60c to 1.70c, depending on delivery, specifications, etc. For anything like early delivery the higher figure has to be paid.

With the steel market quiet, and likely to stay quiet, according to precedents, during July and August, the chief interest is as to the market for the late months of the year. Among sellers, predictions are made freely that buying will be resumed after the vacation period just where it was left off. Among buyers hopes appear strong that conditions will continue good, but no certainty is expressed. In many quarters a note of warning has been sounded, that market activity will depend largely upon prices and may be interfered with if sellers continue to push their recently acquired advantage over buyers. Some of the references are in rather strong language, a possible "buyers' panic" being mentioned, the idea being that if this should develop there would be a vigorous effort to liquidate stocks again. These warnings have been making more or less impression on many sellers and in general the market presents a more moderate aspect. Basic prices are very firmly maintained but on the whole there is less disposition to quote extra prices.

Sheet bars are now quite well settled at $35 for third quarter, while recently there were reports of odd lot sales at $37.50 and $38. The $35 price represents a stiff advance as $29 was the general price for the first quarter and this was done on much tonnage for second quarter also. Billets, by inference, are quoted at $35 also, there being no regular trading market.

Pig iron remains quotable at $25 for Bessemer and basic and $24 for foundry, f. o. b. valley furnaces, as for more than two months past, but the figures have become partly nominal and it is possible that the prices could be shaded. At any rate, the common expectation is that prices will be lower whenever the coal strike ends. Freight from the valleys to Pittsburg came down from $1.96 to $1.76 on July 1.

CHEAP CABLE FACILITY TO HELP BUSINESS

CARDIFF, the market city of a wealthy industrial area and the world's great coal port, is particularly desirous of developing a direct trade with Canada, and is determined to let no obstacle prevent its accomplishment. Canada and Cardiff are already linked up by regular direct sailings, and arteries of rails and highways lead from the port to all parts of Great Britain. To further aid the quick transmission of business the Imperial Cable department of the Post Office announce that the pre-war cable deferred service rates have been restored to the whole of Canada. Deferred telegrams between Toronto, Montreal, Quebec and other places in Eastern Canada and Cardiff only now cost 4 1/2d per word, and the average time of transmission by the Imperial route is within 1 1/2 hours. The Imperial is the only Atlantic cable under purely British control and worked direct from London to Halifax, N. S.

Cardiff has direct through communications with London where expert cable operators transit across the Atlantic, the system in operation combining speed and accuracy in working, so essential to the business man of to-day, and this specially quick service is at rates not exceeding other routes, while for certain parts of Canada the deferred rates are 1 1/2 a word cheaper. The facilities given by the Imperial Cable should materially assist in the development of trade between the Mother Country and the colonies, and it is interesting to note that although specially low rates are charged, the cable is making a satisfactory profit which goes to the direct relief of taxation. The same facilities offered by the American cable companies are also available by the Imperial route.

In return for a nominal royalty of 25 cents per ton on ore mined, the British Empire Steel Corporation has undertaken to construct in Newfoundland before 1928 a plant capable of producing 100 000 tons of iron or pig iron annually, according to an agreement between the corporation and the Newfoundland Government, just completed. The corporation further undertakes to erect coke ovens and to expend $3,000,000 in Newfoundland before 1926.

News From the Industrial Field

The Hidrokarbo Fuel Appliance Co., Toronto, are building a new heating boiler of the vertical, spiral, tubular type.

The Shell Oil Co. of Canada of Montreal will erect warehouses and storage tanks in Hamilton, Kingston, London and Windsor.

A. F. Byers and Co. of Montreal has secured the general contract for the erection of the International Harvester's warehouse in Montreal.

The Canada Machinery Corporation, Galt, recently increased their force by twenty men, due largely to the improved demand for woodworking machinery.

The construction of two dams has been commenced by the B. C. Electric Ry. at Stave Lake. These will be built by day labor at an approximate cost of $1,250,000.

The C. Turnbull Co. of Galt, Ont., makers of underwear have acquired adjoining property that will add 8,000 sq. ft. of floor space for manufacturing purposes.

Toronto Transportation Commission in their work of renewing the tracks and rolling stock of the Toronto street railway have already drawn on requisition, $11,624,115, from the city council.

Building permits to value of $41,215 were issued in Oshawa for June. This is much lower than May but it brings the aggregate for the first six months beyond the quarter million mark.

The town of Thessalon, Ont., will build a power plant and system at a cost of $50,000. Jno. O. Coulter, town clerk, is now receiving tenders for construction work.

The Steel Co. of Canada, Hamilton, has received the steel contract in connection with the $200,000 physicians' bldg. to be erected in Toronto. Contract for steel sash goes to Henry Hope and Sons, Toronto.

Montreal.—Darling Bros. of Montreal announce that they have been appointed agents in Canada for the Nash Engineering Co. of South Norwalk, Conn. manufacturers of the Jennings hytor vacuum and low pressure boiler feed pumps.

Reports from Toronto City Architect's Dept. indicate that building permits are beginning to slacken. The value of those for the first week of July aggregates approximately $725,000, as compared with values well over the million-dollar mark in the corresponding weeks in both May and June.

The C. P. R. Co., announce the appointment of H J. Humphrey to the position of assistant general superintendent. H. J. Main is promoted to the position of superintendent of the Trenton division.

The Foundation Co. of Montreal nas obtained the general contract for the erection of an office building at the corner of Sherbrooke and Grey Sts., for the Medical Arts Bldg. The cost will be about $1,000,000.

The water works plant of the town of Tecumseh, Ont., has been acquired by the town officials, who will henceforth operate it. The town will construct a new filter plant and system at a cost of about $9,000.

The Horton Steel Co. of Bridgeburg, Ont., have secured the contract for steel for a new school to be erected by the Board of Education. Sheet metal work will go to Thos. Irwin and Sons, Hamilton.

W. F. Frizzel, for twenty years superintendent of the Glace Bay power plant died on June 29, following a stroke of paralysis which he suffered on June 27. He had been unwell for some months, was a native of Hills County, N. S. and was 65 years of age.

J. G. Benedict, general manager of the Landis Machine Co., Waynesboro, Pa., sailed July 8th for a combined business and pleasure trip abroad. Mr. Benedict will be away for about two months and his itinerary will include England, France, Holland, Belgium and Germany.

Advices from Montreal indicate that the larger industries are contributing in no small share to a good volume of business in machine shop supplies. The orders are scattered also among the smaller shops, and jobbers declare that this trade is one of the redeeming features of general business.

In order to train export managers in matters pertaining to international trade, foreign tariffs, selling methods abroad, economic geography, trade cycles and currents, courses are being arranged by the department of Trade and Commerce at Ottawa to begin in the universities of Toronto, and McGill, January, 1923.

Extensive additions and repairs are contemplated by the Dominion Iron and Steel Co. to their plant at Sydney, N. S. Several new furnaces and heavy repairs will be carried out. Included in the equipment required will be electric machinery, wire, cranes, steel, fire brick, etc.

Construction operations will soon be resumed by the C. P. R. on the superstructure of the new pier being built at Vancouver for the accommodation of their Pacific liners. It is expected that the work will require at least 12 months and several hundred men will be engaged. The finished pier will be 850 feet long and 330 feet wide, the cost being approximately $2,000,000.

Industrial accidents are always regrettable incidents, and the Government report for the past half year showed a considerable increase over previous months. The inference, however, is the fact that these statistics reflect a relatively large increase in industrial activity, as past records show that the accident ratio corresponds closely to the volume of industrial enterprise.

The following new members have been added to the directorate of the British Empire Steel Corporation: Hon. C. P. Beaubien, Hon. Viscount Furness, Sir Trevor Dawson, Major-General Sir Newton J. Moore, K. C. M. G., M. P., Rt. Hon. Lord Invernairn, Hector McInnes, K. C., Dr. W. L. McDougald, Frank Ross, J. F. M. Stewart and Benjamin Talbot, J. P.

Contract for the construction of 3,000 houses at Ojibway, Ont., has been awarded to J. H. Jewell, of Windsor, by the Canadian Steel Corp. It is the intention of the corporation to develop Ojibway along the lines of a model town, and in addition to 3,000 dwellings a post office, police and fire stations, etc., will be erected. Work will be done by day labor.

A report from London, Eng., states that the London Canadian Corporation has set out to interest big British firms in the Canadian industrial field, and inducing them to locate branch plants in the Dominion. They bring to England expert knowledge of the Canadian situation and undertaking, when negotiations are completed, that one half of the capital required for the new venture shall be found in Canada.

Montreal.—An increase of nearly two and a half million bushels in the amount of grain shipped down the Lachine Canal in June 1922 over that of June 1921 was reported at the canal office when the records for the month had been completed. All varieties of grains showed an increase. In June 1922 there were 63,500 sacks of flour shipped through the canal, while in the same month a year ago there was none. Produce shipments showed a gain while there was a heavy falling off in coal shipments.

Announcement has been made of the shipment of an unusually large consignment of copper-nickel matter from the smelter of the Mond Nickel Co., at Conniston, Ont. With the re-opening of the International Nickel Company's refinery at Port Colborne, this augurs well for the early resumption of activities in the Sudbury Nickel district.

Exports of Canadian pulp and paper in May were valued at $8,522,830, compared with $6,490,359 in April, and $7,929,525, in May, 1921, according to a statement issued by the Canadian Pulp and Paper Association. United States received the greatest share of exports, accounting for $7,034,141. The United Kingdom came next with $187,153, followed with all others, $401,536.

Antimony Products Corporation, a new organization, it is reported, has taken over and is now operating the antimony mines at Lake George in New Brunswick. The new company is now incorporated in the State of New York and has some large contracts for crimson and golden sulphides with some of the largest rubber companies in the United States.

Copper shipments to the Atlantic refineries from British Columbia continue to be above 1,200 tons per month, and the advance in price, together with the increased demand, has brought the copper mining industry to the front again. Domestic manufacturing activity has increased to the point where the big brass mills must have larger quantities of copper with which to fill current requirements.

The strike of coal miners in the States has reacted advantageously for the coal fields in Nova Scotia. At the present time there are about 21 cargoes a month being delivered at Montreal in six vessels operated by the British Empire Steel Corporation. It is anticipated that at least 1,500,000 tons will reach Montreal from Cape Breton before the navigation season closes.

A report issued by the Ontario Mining Institute, shows that the mines of the province had a gross production in 1920 to the value of more than seventy-three millions, and that $30,492,249 was paid out for supplies of all kinds. The gross bill for wages amounted to $25,764,461. The fifty six million odd disbursed exceeded the gross value of all Canada's exports during the same period.

As a result of orders received for overseas markets the plants of the Wayagamack Pulp and Paper Co., of Three Rivers, Que., are reported now running at full capacity. The increase that has come recently has necessitated operating the plant the full 24 hours a day. Present enquiries would indicate that full capacity production will be the order for several months to come. In addition to the outside business, there has also been a noticeable improvement in the demand from the home market.

Four money by-laws authorizing the city to spend more than a half a million dollars on local improvements, extension of the waterworks, etc., were carried by large majorities in the city of Hull, Que.

The Chas. A. Strelinger Co., Windsor, have secured one-half of the entire contract for machine tools let by the Sarnia Board of Education for their new technical school and collegiate institute. Their order consists of five lathes, two gas furnaces, one electric furnace, torch-weld equipment, grinder and anvil.

Montreal.—C. B. Foster, assistant general pasenger agent of the Canadian Pacific Railway states the traffic has been exceptionally good over all the lines of the C P. R. as far as tourists were concerned. This year this business has been so far much better than it was last season, and bookings already indicate that it will keep up during the whole of the season. Both Grand Trunk and G. T. P. have had a busy tourist season so far.

Demand for lumber continued greater than production during the week ending June 10th, according to the weekly review of the West Coast Lumbermen's Association. Lumber cut during the week under review totalled 88,337,001 feet, with sales of 94,180,847 feet. Production of the 122 mills reporting was 9 per cent. above normal capacity. Thirty-five per cent. of the sales were for water shipment.

Windsor, Ont., is to have another automobile industry and will enjoy the distinction of being the first city in Canada to turn out steam cars. The name of the new concern is Windsor Steam Motors, a branch of the Trask Detroit Steamer, which is now turning out a moderate priced steam car in Detroit. Until the plant here is ready it is the intention of the Canadian concern to secure machines from Detroit to take care of the Canadian market.

Thirteen hundred manufacturing plants, employing some 17,000 persons, are located in British Columbia according to J. A. Cunningham, president of the British Columbia Manufacturers' Association. At the beginning of 1922 investigation showed thirty-one lumber companies and thirty-four general manufacturing plants added to British Columbia during 1921. The volume of business of basic industries was: agriculture $60,065,000; mining $23,066,641; lumber $64,970,000; fishing $22,329,000; other industries $58,000,000.

Montreal.—Mr. H. A. Terrault, the new director of public works claims to have saved the city of Montreal $120,000 in six months through the fact that a steam-driven thirty-million-gallon daily capacity pump has been changed to electric drive. A staff of about twenty five men have been dispensed with, and expenses all along the line had been reduced. The maintenance work was less and even the machine shop staff had been reduced. At the same time it was declared that ample provision had been made to take care of an emergency situation which might be created by the electrical power being cut off.

What is believed to be the first electrically operated dredge in Canada has been constructed by the E. O. Leahey Co., an Ottawa firm, at the Victoria Island shipyard and is now enroute to Kingston. It will be used in connection with the construction of the Queenstown Power canal. It is proposed to operate the dredge off hydro-electric power lines. Its estimated capacity is from eight to nine thousand yards per day.

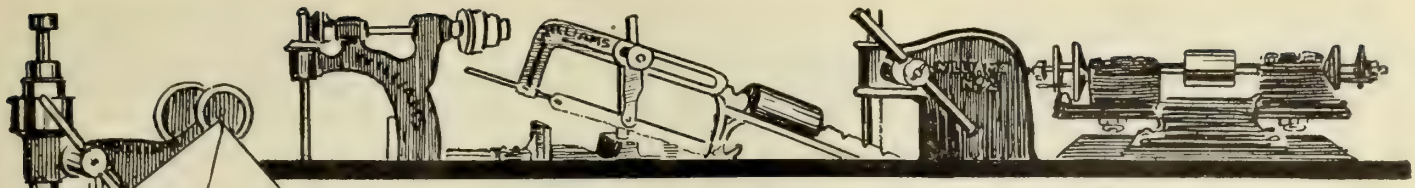
The board of control has decided in favor of proceeding with construction of the two city swimming baths on the basis of amended specifications which will make the cost of the baths $128,964 plus the architects' fees. The recommended tenders are: King Edward Avenue bath, Ed. Monette $60,500; Plouffe Park bath, A. Christie & Son, McDougall's Ltd., $68.454. Only authorization of the City Council is now required.

Montreal.—On July 5th, twenty-five Montreal aldermen visited the plant of the Canada Iron Foundries at Three Rivers at the invitation of the company. On their return, the aldermen stated that they were favorably impressed with the equipment of the company for manufacturing both small and large sized pipe.

The company have just completed the installation of equipment for the manufacture and testing of cast iron water pipe up to 48 inches in diameter, which is claimed to be the largest size pipe ever manufactured in Canada on a commercial basis.

Ottawa.—Complaints have reached the Hon. J. A. Robb, minister of Trade and Commerce, that higher rates are being charged for the movement of grain in Canadian lake carriers from Fort William to Port Colborne, than for transportation in United States vessels from Fort William to Buffalo. This is explained by the fact that certain vessels registered in the United States, which were formerly engaged in other classes of trade, are now readily available for the shipment of grain. Coasting laws prevent United States carriers from discharging their cargoes at Port Colborne. Thus Canadian grain is being diverted to the United States routes at Buffalo. There is, at present, no authority which can control steamship rates and the coasting regulations do not permit of competition having its full effect, regarding trade between Canadian ports.

Another complaint that has reached Mr. Robb from purchasers of grain exported to Great Britain by way of New York. The allegation made to the minister is that wheat reaching England does not grade as high as when it left the Canadian terminal elevators at Fort William and Port Arthur. The inference thus is that it has been subject to mixing between the shipping point and its destination.



Bargains in Re-manufactured Machinery

JUST now there are some particularly good buys being offered in Williams' Monthly Machinery List. Possibly there is just the machine you need: one that you can profitably use in the place of one that is not working satisfactorily.

Every Williams re-manufactured machine is guaranteed by us to be equal to new for all practical purposes.

If you are not receiving our Monthly Machinery list, write us and we will put your name on our mailing list.

Rice Lewis & Son, Limited

Established 1847 TORONTO, ONT. 19 Victoria Street

A tape rolled into German bolts of cloth going to South America markets by which yardage may be told at a glance is described as an "innovation." It can hardly be so, since British manufacturers have been using this plan regularly for the past 25 years.

Montreal.—Contracts have been given out for the building of the new Chalmers Presbyterian Church. The main contract is for the sum of $38,834.00. The Dominion Bridge Co. Ltd., have the contract for the steel work at $2,743.-00 and D. A. Bethune Ltd., the plumbing and hot water heating for $6,450.00.

Ottawa.—Canada's purchased ice-breaker, the John D. Hazen, which was turned over to the Russian Government during the war, held by the French Government at Cherbourg and subsequently purchased by the Canadian Government shortly after the present government took office, will it is stated be on her way to Canada by the middle of July. The steamer will be used for ice-breaking work on the St. Lawrence.

Resumed negotiations between the British and Newfoundland Government and the Armstrong Whitworth Co. of London, may result in the establishment of a large paper making industry on the west coast of Newfoundland. This project was abandoned last winter owing to the failure of the Island Government to guarantee the necessary bonds. The present proposal calls for each Government to guarantee bonds to the value of $10,000,000; it is stated that the British Government have agreed to assume their portion. The Armstrong, Whitworth Co., may offer to purchase the interests of the Reid Newfoundland Co., one of the original promotors, and carry on the undertaking alone.

Mr. George Bertram, of the Lincoln Electric Welding Co., Toronto, is now associated with the James Fisher Co., 384 Yonge St., Toronto. Mr. Bertram will be vice-president of the Fisher Co., and will also have charge of accounts. His previous experience should be extremely valuable, as he has been engaged in many lines. He was at one time business manager of the Canadian Courier also Canadian Farm and has been president and secretary of the farm papers association.

Sydney, N. S.—Monday, July 10, the open hearth furnace of the Sydney Steel plant commenced making steel. This is the first time since November 22, 1920, and the pay roll in Sydney has amounted to $10,000 per day, according to reports from the British Empire Steel headquarters. In the lowest period of the depression there were but 1,300 men working three days a week. Business has been improving for the last three months, and everything points to continued improvement. Local business is reflecting the increased industrial activity. The mines are now on full time filling orders from Quebec and from the northern New England States.

ANGUS SHOP ASSESSMENT DOUBLED

On Friday, June 30, the committee of Montreal aldermen appointed to look into the question of the assessment of the C. P. R. Angus Shops agreed to a compromise in their recommendation that the amount be fixed at $2,000,000. This exactly doubles the figure suggested by the executive committee. For the past twenty years the shops have been assessed at $400,000. This year the agreement expired and the C. P. R. suggested that the new valuation be $750,000. Then the executive committee fixed the figure at a million dollars. The final figured arrived at is now two millions. This assessment is subject to the company employing not less than 3,000 men, and is to remain in force for five years.

FORD COMPANY TO DOUBLE

Ford Motor Co., of Canada have just completed a million-dollar land purchase along the Detriot River at Ford, Ont. It is officially announced that the Company proposed spending between five and six million dollars on the next three years in plant development there. New machine shops will be erected besides forge shops, foundries and body shops, and provision is to be made to manufacture certain materials entering into the completed product of the firm. The new river front property will be devoted largely to dockage and shipping facilities, as the Company has in view extensive plans in connection with development of export business. A new power plant will probably be erected and the capacity of the present plant increased from 250 to 300 cars a day.

To aid the quick transmission of business, the Imperial cable department of the British post office announce that the pre-war cable deferred service rates have been restored to the whole of Canada. Deferred telegrams between Toronto, Montreal, Quebec, and other places in Eastern Canada and Cardiff, Wales only now cost 4½d per word, and the average time of transmission by the Imperial route is within -½ hours.

Montreal.—The erection of two new schools for girls has been decided upon at a meeting of the Catholic School Commissioners. The first, 160 by 60 feet, will have seventeen class rooms and will be three storeys high. There will also be a residence for the teaching sisters. The contract, awarded to Ovila Filion, amounts to $175,800.00 to be commenced immediately. The second will have eighteen class rooms and a kindergarten, and will be 151 by 64.

T. Edwards Hewitt, manager of the Canadian office of Jones and Shipman, the British house of machines and small tools at Leicester, England, tells Canadian Machinery that their business in Canada shows decided improvement. This firm have now been located in Canada for the past three years, and are at present located at 163 King St. E. Toronto. Mr. Hewitt says "We have recently secured some very satisfactory orders for our equipment to be used in technical schools in Canada and this is all the more pleasing because we secured the business in the face of keen competition from foreign makers."

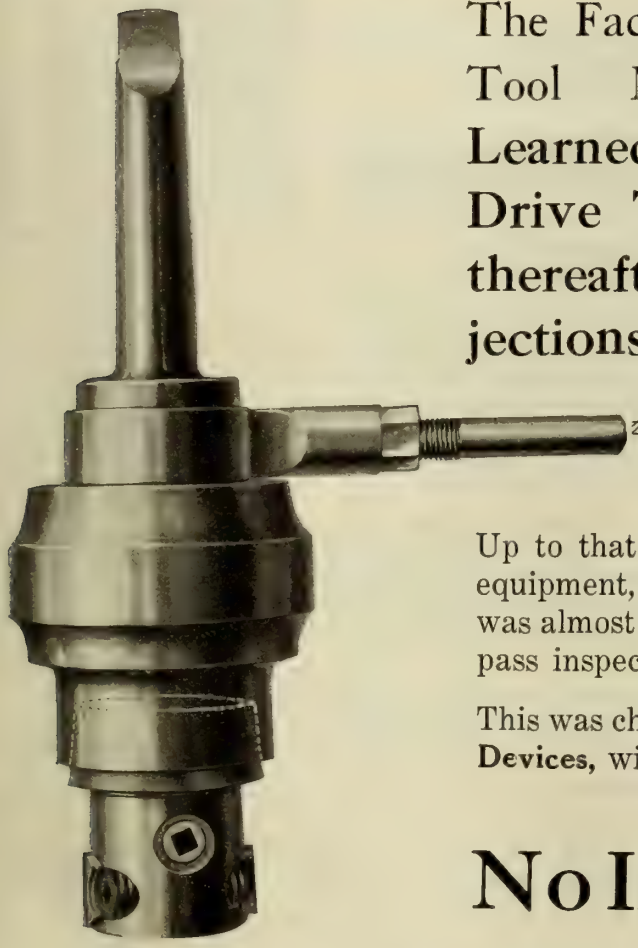
St. John, N. B.—Under date of July 5th, it is announced that the court of inquiry concerned under Captain L. A. Demers, Dominion Wreck Commission, find that the bridge tender of the Morrisey Bridge at Chatham, N. B., or his employer, the New Brunswick Provincial Government, is responsible for the C. G. M. M. Steamer "Canadian Squatter" colliding with the structure. It was found that the pilot followed a dangerous practice in going too near the bridge but the majority finding of the court, of which Captains McLean and Mitchell are members, relieves the pilot and shipmaster from any blame. Their certificates were returned to them. Captain Demers recommends more clear definition of the caretaker's instructions, and that regulations governing pilotage be framed by the Harbor-master.

Powley and Moody, 105 Bond St., Toronto, are finding their radio business exceedingly active. They are representing the Millard Radio Valve Co. of London, England, the latter mentioned firm being contractors to the British War Office, Admiralty Royal Air Board, Post Office, and other public institutions. The Millard Co. make a very complete line of reception and transmission valves, the latter from 20 watts to 10 k.w., including the well known "Silica" valve for high power stations. The leading valve made by this company is known as type O. R. A. the name applying that it oscillates, rectifies and amplifies. It is said to have very long life, and operates on low current consumption. It has the distinct feature of being noiseless according to the makers. M. G. N. Middletown, E. E. is vice-president, and C. A. Lowry radio engineer for Powley and Moody are directors of Radio Devices Ltd., Gananoque, Ont., Powley and Moody being selling agents for the latter mentioned line. Between both activities they are very busy.

NEW USE FOR CANADIAN WOOD

In the construction of storage batteries for automobiles it is necessary to use considerable wood, made in very thin corrugated sheets and designated as separators. Wood for battery separators must possess special chemical and physical properties and until very recently the wooden separators used in Canada were made almost exclusively of imported woods. The Forest Products Laboratories of the Forestry Branch, Department of the Interior, recently undertook research to determine whether any Canadian wood was suitable for separator work, and as a result found a most excellent material in the yellow cypress of British Columbia.

Worked Like Magic



Note the dotted lines illustrating position and size of friction Cone

The Factory Manager of a large Tool Manufacturing Concern **Learned of the Jarvis Friction Drive Tapping Device and thereafter there were no rejections.**

Up to that time they had been using regular standard equipment, and the bottoming taps did not bottom. It was almost impossible to tap the holes so that they would pass inspection.

This was changed like magic when the 20 **Jarvis Tapping Devices,** with **Cone Friction Drive,** were installed.

No Inspection Needed

The Jarvis Friction Tapping Device taps the holes to bottom, and then runs in a second time to do its own inspecting, and, when it finishes, every hole is thoroughly cleaned out to bottom.

Very little pressure is needed to drive the Device.

The Drive is controlled by pressure on the machine spindle.

Stripped threads are unknown.

Holes tapped in toughest metal with little tap breakage.

Standard Chuck.

No special taps required.

The Tap is freely started and stopped while rotating.

Adaptable to Drilling Machine or Speed Lathe.

Ask us about the Jarvis High Speed Tapping Devices, which act without clinching or binding.

And the Jarvis Quick Change Chucks and Collets, for Drilling, Counterboring, Tapping and Stud Setting.

We are Sole Distributors

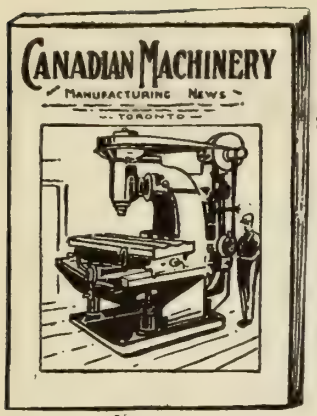
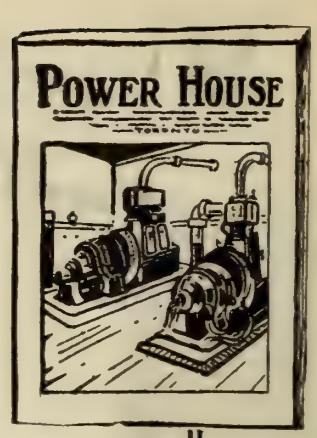
Williams & Wilson, Ltd., Montreal. **The A. R. Williams Machinery Co., Ltd.,** Toronto, St. John, N.B., Halifax, N.S., Vancouver, B.C.





DO YOU Manufacture Industrial Equipment ?

Are you a manufacturer of twist drills, hack saws, mechanics' tools, wire guards, bolts, rivets, paints—do you manufacture lines of any description that can be used in machine shops, metal-working plants, power plants or foundries? If you do the publications you see illustrated here (Canadian Machinery, Canadian Foundryman, and Power House) can build a bigger demand for your products.

This group of technical newspapers is read by the men who are prospective buyers of your lines. You can bring to the attention of these men the reason why they should demand your goods when purchasing from their dealers. You can effectively do this by placing a message in the paper which serves the field in which your products are sold.

CANADIAN MACHINERY AND MANUFACTURING NEWS is published weekly and covers the machinery, iron and steel and general metal-working industries of Canada.

POWER HOUSE is published semi-monthly; it serves steam, electrical, water and gas power plants, and the power houses of all general manufacturing plants.

CANADIAN FOUNDRYMAN AND METAL INDUSTRY NEWS is published monthly; it serves the grey iron, steel and non-ferrous foundries.

Each one of these publications reach proprietors, managers, purchasing agents, foremen—the men who direct the purchasing of goods. A message to these men in any of the MacLean Technical Newspapers is certain to have a strong influence.

Write for complete Data.

HEPBURN

POWER PRESSES

For Long Service—

After all, you could no doubt buy any number of presses that would give the same production the first few weeks of operation. But after a year—two years—three years—What then? If it is a **Hepburn** built Press you get production unslackened by constructional weaknesses.

Hepburn Power Presses are strong and well built. The cranks are made from solid forgings and give long strokes. Quick adjustability a feature of every press. Write for specifications.

We also make Vertical Engines, Compressors, Winches, Planers, Steam Pumps, Cranes, Special Machinery Forgings and Castings.

JOHN T. HEPBURN Limited

Engineers and Iron Founders

18-60 VAN-HORNE STREET, TORONTO, ONTARIO

Carbon Plates,

Rods, and Paste for Oxy-Acetylene Welding

WHERE the flow of metal must be restricted to a definite area, there is no substitute for carbon.

It is impossible to utilize the full advantages of the oxy-acetylene process without carbon dams, retainers, and plugs. Columbia Welding Carbon Products are indispensable in making heavy welds on castings without dismantling; in reinforcing welds to any strength desired; and in simplifying vertical welding.

When answering advertisements kindly mention Canadian Machinery

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

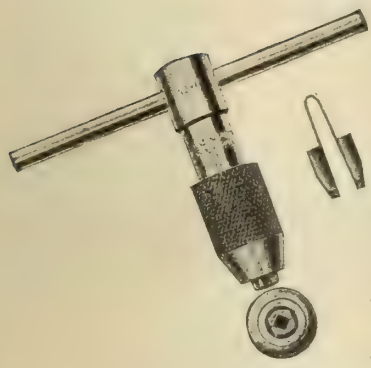
Another New Starrett Tool — T-Handle Tap Wrench No. 93



An exceptionally handy tool. Although especially designed for holding taps to be turned by hand, it will be found exceedingly convenient for holding drills, reamers and many other small tools.

Special clamping construction insures firm holding of tool gripped. A centered body permits this wrench to be used on lathe centers or drilling machine to start the tap straight. Heat-treated jaws and clamping nuts guarantee durability.

You'll find this new No. 93 T-Handle Tap Wrench—like all Starrett Tools—thoroughly practical, dependable and durable. It's a tool you will want to keep handy.

Ask your hardware man to show it to you, with other new Starrett Tools illustrated and described in our special Supplement to Starrett Catalog No. 22 3 Write for a copy of this Supplement—and, if you haven't a copy of the Starrett Catalog No. 22 3 ask for that too. Both free on request.

GUTTA PERCHA & RUBBER, LIMITED
TRADE P.M.S MARK
TORONTO, CANADA

For Better Power Transmission

"P. M. S" Rubber Belting owes its extensive popularity in this country to its excellent adhesion to the pulleys, even pliability, great strength and unequalled ability to resist the effect of heat, cold and moisture. These qualities, coupled with its comparatively low first cost and usefulness for nearly all purposes, have won the respect and esteem of Canada's engineers. It is giving excellent service to-day under conditions once believed too severe for this type of belt.

Manufactured Exclusively by

Gutta Percha & Rubber,

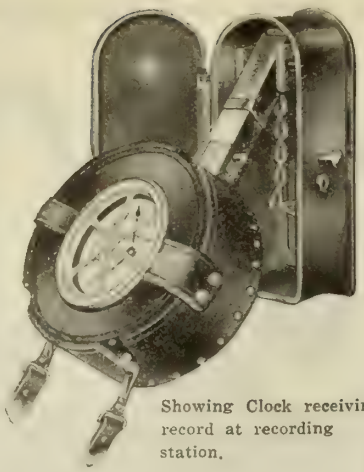
Watch Your Watchman!



Showing Clock receiving record at recording station.

WHEN you pile into your bed every night do you ever stop to realize that you are entrusting, absolutely, the source of your income to a low-salaried watchman **without proof that he is actually "on the job"?** True, you have your fire insurance, but that is merely indemnity for buildings and material destroyed. It pays you nothing for loss of production, organization and time.

The Hardinge Alert System is your Factor of Safety. It tells you, beyond argument, whether you are getting all the protection you pay for. If your watchman is "on the job," it tells you so—if he's a slacker, it tells you so. It cannot lie, the watchman makes the record himself. By his own hand he tells you whether or not he is faithful.

There's no wiring, no complicated installations to the Hardinge Alert; your workman can equip your plant in a couple of hours.

Let us send you a system for thirty days' trial.

DO YOU Manufacture Industrial Equipment?

Are you a manufacturer of twist drills, hack saws, mechanics' tools, wire guards, bolts, rivets, paints—do you manufacture lines of any description that can be used in machine shops, metal-working plants, power plants or foundries? If you do the publications you see illustrated here (Canadian Machinery, Canadian Foundryman, and Power House) can build a bigger demand for your products.

This group of technical newspapers is read by the men who are prospective buyers of your lines. You can bring to the attention of these men the reason why they should demand your goods when purchasing from their dealers. You can effectively do this by placing a message in the paper which serves the field in which your products are sold.

CANADIAN MACHINERY AND MANUFACTURING NEWS is published weekly and covers the machinery, iron and steel and general metal-working industries of Canada.

POWER HOUSE is published semi-monthly; it serves steam, electrical, water and gas power plants, and the power houses of all general manufacturing plants.

CANADIAN FOUNDRYMAN AND METAL INDUSTRY NEWS is published monthly; it serves the grey iron, steel and non-ferrous foundries.

Each one of these publications reach proprietors, managers, purchasing agents, foremen—the men who direct the purchasing of goods. A message to these men in any of the MacLean Technical Newspapers is certain to have a strong influence.

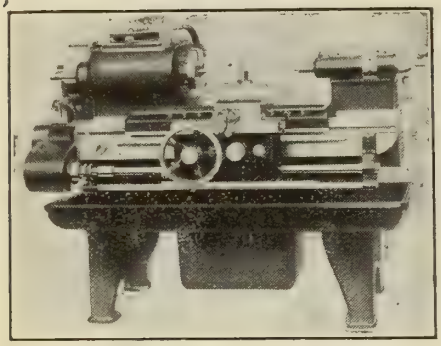
THE JOHNSON FRICTION CLUTCH

AS USED ON THE

"NEW" 12 IN. SUNDSTRAND MANUFACTURING LATHE



Progress in machine tool design demands a reliable and powerful friction clutch.

The Johnson Friction Clutch is proving of great value in machine tool designing.

Courtesy: The Rockford Tool Co., Rockford, Ill.

The main drive pulley is mounted on a No. 5 single clutch hub. The same movement that disengages the clutch automatically applies a brake which stops the spindle instantly. The sliding sleeve is machined to act as a brake.

A feature of the Johnson Friction Clutch is the ease of application to particular machine requirements.

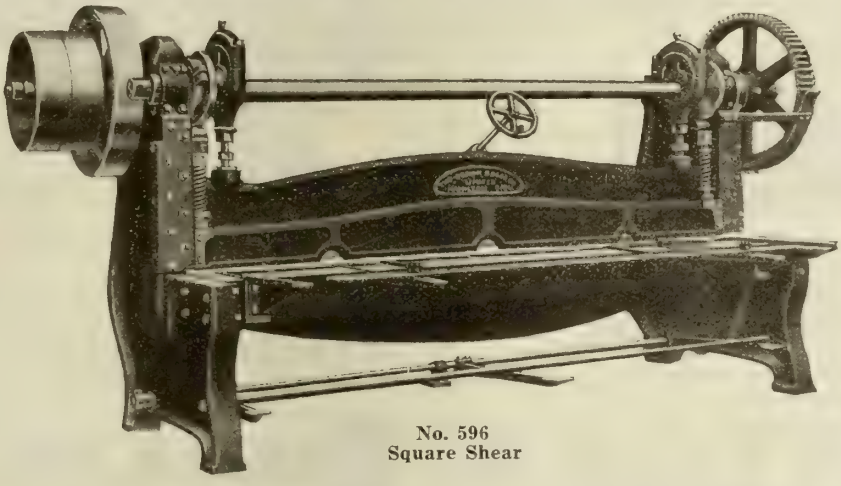
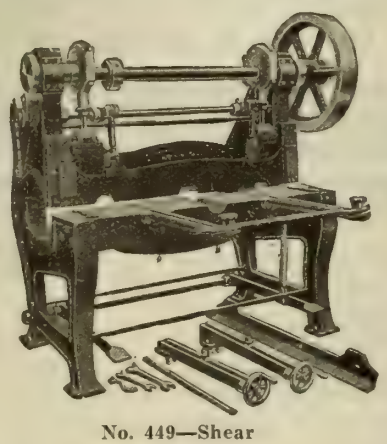
BROWN-BOGGS

B B



No. 596
Square Shear

Foot and Power Shears
that satisfy the workman's own ideals



No. 449—Shear

NATURALLY every workman has his own opinion of how a machine should operate and what it should accomplish.

"B-B" Foot and Power Square Shears always head the list for productive ability—for the simple reason that they line up closely with the workman's own ideals.

The material used throughout is the very best; wearing surfaces are large; gears are machined from solid stock. The knives are carefully tempered and are easily removed for grinding.

"B-B" Power Square Shears are made in "Overhead Driven" and "Underneath Driven" Types. Power Gap Shears in the same types. Foot Shears in many styles.

Catalogue No. 25 gives full details of the complete "B-B" Line of Metal Working Tools. Write for a copy.

STRENGTH OF GEAR TEETH

The Hamilton Gear and Machine Co.

1. From speed and diameter get pitch line velocity in feet per minute, = p.l.v.
2. Horse power × 33,000 = P. power in foot pounds per min.
3. Divide P by p.l.v., giving W, the working load on teeth in pounds.
4. Knowing the kind of material and the p.l.v. (1), get S, the allowable working stress in pounds per square inch from curves in diagram published in our last month's advertisement.
5. Divide W by S, giving K, a strength factor for the conditions of the load.
6. We have already assumed the diameter. Now take any pitch of teeth as a trial and find number of teeth.
7. From the table which we will publish in next month's advertisement find the value of K for a gear of the assumed pitch and number of teeth and of a face equal three times the circular pitch. This K is the strength factor for the assumed gear.
8. From face = 3 × c. p. for strength factor K (7) find the face needed for strength factor K (5).
9. If this gives a badly proportioned gear with too wide or too narrow a face try some other pitch or a different diameter.

See next week's advertisement for diagram, and the following week for table to use in connection with the above.

Why 38 Alundum Grinding Wheels In The Tool Room?

Here are the reasons:

Machine Operator: "I am alright when you send me those red wheels for my Universal Tool and Cutter Grinder."

Tool Room Foreman: "We will use your red wheels now exclusively; they are giving us fine results."

Shop Superintendent: "Those wheels you call 38 Alundum, which we have been getting lately for tools—they're the best we ever had. They cut fast, leave a fine finish and they **do** stand up. And the tools last longer for each sharpening."

Purchasing Agent: "They are still asking for 38 Alundum Wheels out there in the Tool Room, so that's what we will specify on our orders."

For high speed steel tools, or fine sharpening of hardened carbon steel tools, or for surface grinding hardened or high speed steel surfaces, 38 Alundum wheels are particularly adapted.

If you have not tried them, write for full information.

Some Fundamentals of Milling Machine Practice

Reducing Principles to Working Basis—Minimizing Bad Effect of Excessive Impact and Rubbing—Number of Teeth a Governing Factor—Getting Maximum Service of Cutter

By S. R. GERBER, M.A.S.M.E.

PROGRESS in the art of milling can be greatly facilitated by reducing the principles to fundamentals. Unless these are thoroughly established and understood, a description of the methods in use are soon forgotten. When we stop to consider such elementary questions as, "what dulls a milling cutter?" we are brought face to face with facts that are basic in our machine shop problems, the most perplexing of which lose their sting when we unearth the fundamentals. We've often heard it said, in a matter-of-fact way, that the milling cutter should have so-and-so many teeth; that for a fine finish we must run at a low feed and high speed; for rough work we can use high feed and low speed and a number of other rule-of-thumb methods of practice that are handed down from master to apprentice without the reason why; without any conception of the elementary principles.

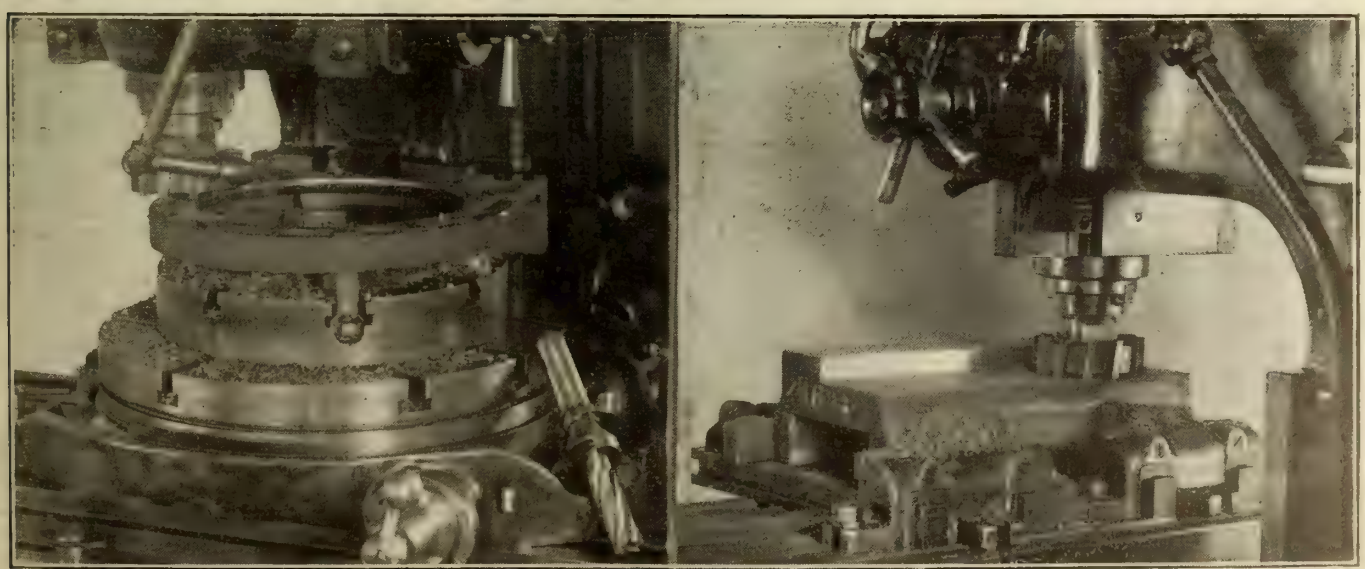
Milling is the removal of metal by means of a tool which rotates while the work is advancing toward it. This differs from the action of a lathe tool only in the length of the chip removed and the frequency with which the tool enters the work. For instance, a lathe tool, (which is stationary—the work revolving), is pushed into the metal and rubs only until the strain on the cross-slide overcomes the resistance of the metal, then it starts removing the chip. The tool is then under operation until the cut is made, when the operator again sets it for the next cut. The milling cutter is a disk with a number of lathe tools inserted in its periphery, and each tool operates exactly like the lathe tool rapidly following its predecessor. In the case of the milling cutter, each tooth rubs on the metal, then the action that follows is similar to that of the lathe tool in taking its cut, but usually not of such long duration.

What dulls a milling cutter? There are four distinct factors entering into the dulling of a milling cutter. They are:—1. impact, when tooth strikes the metal; 2. rubbing, before cleavage takes place; 3. cleavage, actual wedging into the metal; 4. shearing, when metal is being removed.

There are several causes of impact and rubbing during the milling operation. If the milling machine was absolutely rigid with no play in the table or carriage or overhanging arm; if the fixture were built so as to allow no spring; if there was no play in the spindle bearing; if the arbor were heavy enough to allow no spring whatsoever; and, with all that, if the teeth in the cutter were spaced so that one tooth did not leave the work before another entered, then there would be minimum impact and minimum rubbing. But the above specifications are impracticable, if not impossible, consequently, in the degree with which we fall short of these requirements, we reduce the life of the milling cutter.

Since, in practice, we cannot eliminate the causes that dulls the milling cutter, we attempt to ameliorate these conditions as much as possible. The machines are built more rigidly, the bearings and ways are made as snug as practical, the arbor is made large enough to reduce deflection to a minimum, though not too large to increase the size of the cutter to a point where surface speed becomes

Author is president of S. R. Gerber Co., New York industrial engineers.



Modern methods of vertical milling.

a detrimental factor, and the cutter is made with the required number of teeth. These precautions tend to reduce the impact and rubbing to a minimum. Further reduction of harmful effect of the rubbing action is brought about by flooding the cutter with a copious supply of lubricant or coolant. This can hardly be overdone.

The effects of cleavage and shearing are reduced by proper grinding of the teeth of the cutter so as to insure the correct rake and clearance angles for the particular class of work under operation.

Life of The Tool

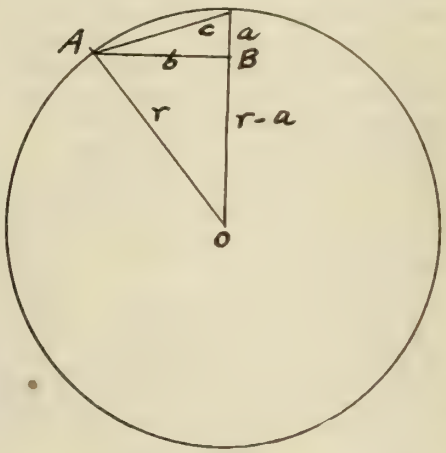
Surface speed, as applied to milling cutters, is a factor in the life of the tool as regards its impact, rubbing and shearing. The impact varies with the radius and velocity of the cutter, and the surface speed is also dependent upon the radius of the cutter and its r.p.m. The amount of wear on the cutter caused by the rubbing actio which takes place on the tooth of the cutter before it "bites" into the metal is also dependent upon the surface speed. And finally, the surface speed has the same effect on the tooth of the cutter as is suffered by the lathe tool during the actual cutting operation.

The feed per revolution per tooth of the milling cutter has a twofold effect on the life of the cutter. First, increasing or decreasing the feed per tooth directly increases or decreases the length of time the tooth rubs before "biting" into the metal. Second, varying the feed per tooth varies the length of time the tool is performing the actual shearing. Considering, therefore, the relative effects of the surface speed on the life of a milling cutter, and the feed per revolution per tooth of the milling cutter, as outlined above, it is evident that **a change in surface speed will have a greater effect on the life of the cutter than a change in feed.**

The life of the cutter can actually be lengthened by increasing the feed per tooth, because by so doing, the length of time the tool is rubbing before entering the metal is considerably reduced. If the feed per tooth were reduced to an extremely fine cut, the probabilities are that under ordinary conditions of milling machines, there would be practically no cutting at all, but merely rubbing—burnishing. And, on the other hand, if the feed per tooth were made very great, the rubbing would be practically eliminated. As the feed is increased, it is, of course, necessary to strengthen the teeth of the cutter, increase the size of the arbor, and generally make the machine more rigid. Evidently, if the arbor is not rigid enough, the deflection would increase proportionately with the heavier feed and the desired effect of reduced rubbing would be lost.

Number of Teeth

The number of teeth a milling cutter should have has received considerable attention of late and, consequently, some of the old rule-of-thumb ideas have been exploded. Fundamentally, the number of teeth a milling cutter should have is determined by the depth of cut. A milling cutter could be used with only one tooth in its periphery. But, during the interval when the tooth leaves the metal and starts around for its next strike, the strain on the arbor and the carriage of the machine has been released, so when the tooth starts to cut again it must take up all the slack, and so on, for each revolution. To avoid this, the teeth must be close enough to permit the next tooth to enter the work before the preceding tooth leaves.



With this in view we have devised a formula for the proper number of teeth in a cutter according to the depth of cut. This formula is limited in use to roughing cuts only because the number of teeth in a cutter used for making finish cuts depends partly upon the feed per tooth.

Let a=depth of cut minus a constant (to be determined); c=pitch of the teeth; n=number of teeth in cutter; r=radius of cutter; b=AB perpendicular to radius.

$$b^2 = \sqrt{r^2 - (r-a)^2}$$

$$c = \sqrt{b^2 + a^2}$$

$$c = \sqrt{r^2 - (r-a)^2 + a^2} = \sqrt{r^2 - r^2\ 2ar - a^2 + a^2}$$

$$c = \sqrt{2ar} = \sqrt{ad} = \sqrt{\pi d}$$

$$n = \frac{\sqrt{n^2 d}}{a} = \frac{\sqrt{9.87d}}{a}$$

Series of Tests

The following is a report of a series of tests made to substantiate the above fundamentals: In these tests a high speed steel cutter was used, 3 inches diameter, with a 1 inch arbor, and the depth of cut 3/32 inch. The cutter was flooded with a copious supply of a soluble oil compound.

The first run was made at 510 r. p. m. giving a surface speed of 400 feet per minute with a feed of .001 inch per tooth and a table travel of 15 inch per min. Under these conditions 2,735 linear inches of metal were cut. We then ground out every other tooth of the cutter, making the feed per tooth .0033 inch and made another run which lasted for only 2,270 linear inches. We have evidently increased the deflection of the arbor instead of having reduced the rubbing time before the tooth "bites." But there seems to be another element which has entered to reduce the life of the tool, namely the chip space. As long as the chip clearance is sufficient for the depth of cut, a greater number of teeth is desirable. In this case we have probably reached a considerable deflection of the arbor and the cutter with the greater number of teeth seemed to keep the arbor in the strained condition while with the cutter with less teeth, one tooth was out of work before the next one "bit" and that released the strain on the arbor and caused the edge of the next tooth to drop on the work. The hammer produced by this action may have been instrumental in dulling the cutter.

To further prove the above assumption we have increased the feed per tooth of the cutter with 18 teeth to the same feed as the cutter with 9 teeth had and our production was greatly increased. We cut 1,280 linear inches at a feed of .0016 inch per tooth and without changing any conditions except increasing the feed per tooth to .0035 inch. We cut 2,444 linear inches more, making a total of 3,724 linear inches on that run.

Our next run was made at 600 r.p.m. or 470 ft. per min. with a feed of .0035 inch, table travel 38½ inches per min. The cutter lasted for 1,310 linear inches of metal. This showed what a marked effect the small increase in speed had on the life of the cutter. This run was repeated and the cutter dulled accident-

Keeping Careful Tab on Factory Operation Costs

Labor, Material, Overhead and Marketing Expenses Should Be Skilfully Analyzed—Contented Employee a Factor in Cost Reduction—Figuring Piece Work—System Essential in Keeping Records—Routing and Planning Work—Economic Methods in Handling Material—Watching the Details.

EVER since currency was introduced as the medium through which we transact business, and probably before that too, the problem of costs has been a very vital factor, not only in machine shops but in all lines of business. The cost problem is a very complex one. It cannot be ignored, for unless costs are known, the chances of succeeding in any business are few. In ninety-nine per cent. of the cases of machine shop activity, costs must be obtained if the business is to flourish and is to be intelligently handled.

One peculiar feature about factory costs is that practically everyone appears to take it for granted that they, as a unit, can be represented by a definite figure. Such is not the case, because in every set of cost figures there are always certain assumptions.

In connection with machine shop costs, one can classify the component items in a large number of ways. The classification that is probably the simplest, and appeals to most shop owners, is to divide the cost item into the four following sub-divisions, namely,—labor costs, material costs, overhead expenses, and the cost of marketing. On this division we will attempt a general analysis of costs as applied to the average machine shop.

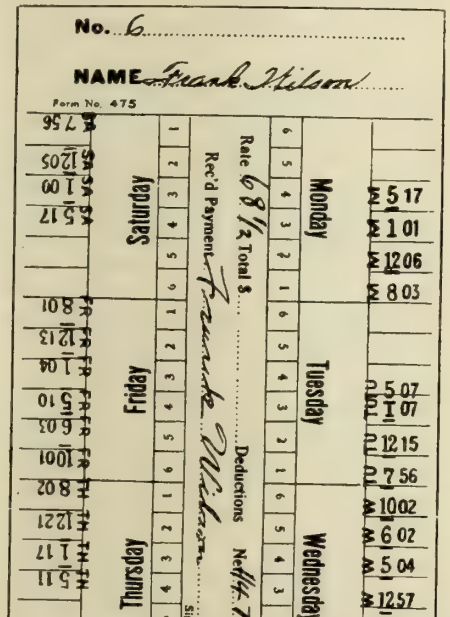
Labor Costs

In a large majority of instances, labor cost is the heaviest individual expenditure in a machine shop. As labor is paid largely by the hour, there is no better method of keeping a basic record of time than by means of one of the many designs of time clocks. In using time clocks it is very essential to have each employee record his own time. The details of how this can be best accomplished will have to be arranged for each individual shop. After this is arranged it should be seen that workmen proceed rapidly to their various duties. Similarly, foremen should see that workmen continue at their posts until quitting time. It is altogether too common a fault to see workmen slow up, or quit entirely, as the clock approaches the quitting hour. Much has been written along these lines, which leaves little room for further elaboration in this article.

Therefore, we will assume that arrangements have been made to check the number of hours worked by each man. Now each man is drawing down a certain sum for every hour worked, and in return he is expected to accomplish certain work,—to produce something. The average man is honest. He does his best, but what that "best" is, largely depends on a variety of conditions. Men produce more, and are at their best, if their mental attitude is one of contentment. Thus, in as far as cost is concerned, the only logical thing to do is to surround workmen with conditions that are conducive to contentment. Good light, both natural and artificial, is necessary. The shop must be neat and orderly. The lavatories and wash rooms should be clean and sanitary, the heating should be sufficient to maintain the buildings at the proper temperature, and the ventilation should be ample. All of these factors have very direct influences on a man's ability to produce, and this directly affects the cost figures.

To Satisfy the Average Man

Methods of producing a happy em-



Employee's weekly time record.

ployee through sporting and athletic societies, welfare and benefit movements, cafeterias, social intercourse, etc., have been advanced and tried out with varying degrees of success. In some cases there is no disputing the fact that they are valuable, and we have no word of condemnation. However, the employees often ask themselves if these things are necessary. The average man likes, in as far as possible, to be guardian of his own destinies and custodian of his own funds. Why not give the employee a square deal with this thought in mind? Any effort on the part of the firm, which may emanate from the best of motives, but which smacks of paternalism, is resented, mentally at least.

As suggested previously, provide men with good working conditions, sanitary, well heated and ventilated factories, give him good machinery and tools, and an opportunity to earn good wages, and you have satisfied the average man. Elaborate arrangements to entertain him in the noon hour, to care for him when he is sick, to attempt to guide his pursuits out of working hours, do not tend to satisfy the better class of mechanics. They know that all such activities cost the firm money. Why not distribute this money as wages or bonuses, and give the man directly all that he is worth? Allow him to distribute his earnings as he sees fit. Make him a responsible party. He comes to work for wages, not to be entertained. By giving a mechanic the ultimate in wages directly, you appeal to him in the most direct way. He values the trust and responsibility, becomes a more contented employee, and more loyal. Now these remarks appear to be a long way from costs, but upon close analysis they are found to be very directly related. A little money spent in bringing about the above conditions, will reduce costs to an extent that is very gratifying and is well worth the investment.

It is not intended to convey the fact better judgment is to be cast aside, and hard and fast rules adhered to. There are no two conditions alike and the far-sighted shopman can often see where his special conditions require treatment that would not ordinarily be advocated in a general way.

Piece Work Basis

Labor is often paid on a piece-work basis in manufacturing shops. This is an effort to control labor cost. Properly administered, a piece-work system is desirable. Machinery should be properly tooled, and properly speeded, and every effort put forth to discourage abuse of equipment. Many firms advocate methods of paying for piece-work along lines other than that of paying on the daily output. The average monthly output reduced to a figure per day should be considered as a basis of payment. Then shut-downs would become expensive. One firm even went farther than this, recently, and calculated its piece-work output over a six month period. That is to say, it took the output of the month just completed, and added to that the output of the previous five months and divided the total by six.

This sum was considered to be the piece-work for the current month on which remuneration would be paid. Thus results of either a good or a bad month would be felt for six months. It is claimed that the system is tending to do away with the abuse of machines. Inspection records show up good producers in men and machines, and many very valuable pieces of information can be obtained by intelligently analyzing these records.

Importance of Accurate Records

The method of checking time is a very broad question. The initial step, as before indicated, is by means of the time clock, which records are usually required in order to figure the payroll. Additional records are required to determine those items against which the payroll can be charged. In the small contract and jobbing shops each order should be given its number and duly entered. Following this, the shop foreman or superintendent should be advised, and the proper card entries made out. The job would then enter into the planning of the shop work and its various schedules and routing considered. A careful foreman would plan his work in such a manner that he would use all his largest, and good revenue producing machines to the very best advantage. Frequently, orders call for castings, and when such work is being planned and routed in advance, delivery dates from the shop's own foundry or an outside concern would have to be definitely ascertained. Then with this information, the execution of the work could be intelligently planned.

While on the subject of castings, it is well to bear in mind that castings are sometimes lost, and schedules have to be frequently revised to meet such unforeseen conditions. Files in the foreman's office should be complete, and each piece of work in the course of manufactures should be tagged. The machine number, date, operator or machinist, and the time operation started and finished, should be completely recorded for each sub-operation and operation on each piece. From these records, time and labor costs can be accurately calculated. It is not only important that the time spent on each and every piece of ordered work be recorded, but a machinist should be taught to account for all of his time, distinctly indicating the exact time that was spent in non-productive labor.

Some shops are content to have the eight or ten hours, which constitute a day, spread over the various jobs, with no indication of the fact that there may have been more or less non-productive time put in by the mechanic during t working hours. The non-productive t me we refer to, is that time spent in maintenance work such as mending belts, oiling machines, etc., as well as time spent in looking up or obtaining jigs, fixtures, straps, bolts, blocks, tools, and other equipment. If a man were inclined to allot too much time to actual productive machining time, he would soon be classed as a slow man. On the other hand if his reports showed an unusual amount of time consumed in non-productive labour, his record would attract attention. If it was found that he delayed or loafed between jobs, it would be to his own disadvantage. If it were shown however, that shop conditions were such as to cause a large amount of time to be lost in this way, these conditions would be apparent and would naturally come in for attention.

A Fertile Field for Losses

It is always a good policy to collect shop data on time records, in such a way that the allotment of the total time of the man can be shown, the total time on each individual revenue producing job shown, and lastly it is often very useful to reduce the above to production per man or per machine. Various organizations of the machine shop would determine different methods of collecting and recording the information, which to be of most use, would be tabulated according to the special requirements of the job in hand. Some direct deductions that can be made from these tabulated records would be those showing up of the best men and the best machines, and conversely the limelight would be thrown on the slow movers in men and machines, and lastly any unbalancing or congestion of the shop would be apparent. Such deductions are of special use to the jobbing shop of small or medium size.

It is often stated that the obtaining of these records costs too much. The simpler ideas should be made use of, at first, and then gradual improvements can be made. There is a point in the obtaining of labor cost records, beyond which it is not advisable to go, but this point differs in every shop. It will be found that by slowly building up a system, the new ideas will function better after a little time, and that the information obtained will save a far greater amount than it costs, if common sense is used in the methods put in use.

We cannot seem to forget that labor is usually the largest item on the cost list of machine shop products and it only seems natural that it should be given proper administration and guidance. Such a course often enables a shop to turn a probable loss into a profit, or a small profit into a larger one. In fact there is no more fertile field for losses than in the payroll.

Routing and planning work in a contract or jobbing shop is a very important item, as the two conditions often set up—the demands of rush work, and those of economical routing,—are frequently conflicting.

In the problem of guiding and employing labor in the shop handling varied work, there is no system that seems capable of taking care of all the different conditions met with, and for that reason the shop owner and the foremen should always consider the methods of getting the maximum production from the labour employed.

Tactful Leading Necessary

Probably few people realize that one of the greatest assets of a machine shop foreman or superintendent is his personality,—his tactfulness. Good machinists do not need to be driven, they should be led. Swearing at a man, or using any form of language that emanates from anger or passion, puts the average self-respecting man in a frame of mind that makes it difficult for him to produce for periods varying from an hour to a week, according to the man. We have never yet seen any good come from a heated argument. Thus a tactful, sympathetic foreman, who understands human nature, as well as he does modern machine shop practice, saves his salary many times over, because he does not place men in those frames of mind that makes it difficult for them to produce to advantage. He saves many hours every month. Now every hour saved is a reduction of the

Showing cost of machine work.

cost of the work passing through the shop.

It is not within the grasp of every machine shop to have the very best in machine tool equipment. Nevertheless it is always advisable to place first class men on first class machines. When this is done the quantity and quality of the work accomplished permits the shop to pay the prevailhigh wages and still make a profit. Records of work passing through the shop should always indicate the daily capacity of each machine, in both the case of manufacturing or contract work, so that the slow producers would be shown up. These are the machines that add to the cost. Careful investigation should be made in order to determine how long it would take a new and up-to-date machine to pay for itself. In this calculation, it must be borne in mind that the labor costs per diem on the two machines will be identical, and as far as labor is concerned, any increased production on a new machine would be clear profit.

In the larger shops, where manufacturing is done exclusively, the problem takes on a different aspect. The work goes through in lots and a rigid inspection system follows it up. The spot light is thrown on most of the weak points, and an organization is available to work up records making complete and exhaustive analyses. For that reason, the labor problem in some respects, is simpler in the larger shops.

In all classes of shops, a large labor turnover is an extremely undesirable feature. Irregularity in labor is another source of excessive costs. At all times great care should be taken to keep the agitator or chronic kicker on the outside of the factory walls.

Finally, the tactful handling of labor, providing good working conditions, good tools, and showing a desire to be human and sympathetic, does a great deal to eliminate waste and to reduce labor cost. Treat men well, and the good that is in them will respond to that treatment. Be tactful, but above all, be master of the situation.

Material Costs

The cost of material truly is deceptive. It looks a simple item, and one is apt to overlook some of the smaller items that it drags in its wake. Iron, steel, brass, and copper can be usually charged up at so much per pound, and the quantity can be obtained by direct methods.

Indirect costs, such as interest on investment, when large quantities of material are kept over long periods, insurance on same, and possible loss through theft or exposure to the elements, must be kept in mind. The problem of the falling market sometimes causes relative costs to mount. The rising market is only a point to be considered in figuring selling prices. It is often found that the scrap pile yields up A-1 material for certain work. In the event of scrap material being used, the shop should credit itself with the actual market value of new material, and this item would enter into the costs. Thus an equitable selling price could be established, as most selling prices are figured from the cost figures. These unexpected advantages should be capitalized for two reasons. The first reason is that the advantages are useful in couteracting unexpected disadvantages, and secondly if a low selling price were established on the article, the purchaser would in the future base his idea of the cost of the article on the original low price and subsequently if new materials were used, the article could not be reduced for the original low figure. A department to salvage waste material, is the means of saving a good deal of money at times, and is nearly always a paying investment.

The careful storing of all incoming material at a point or points convenient to the places where such material is to be used in the shop, eliminates lost time in routing such material to machines. If the stores are in the hands of competent men, who use card indexes and permanent inventory systems, handling costs will be kept at a minimum level. It is often the little things that are missing or short, that cause certain machines or departments to be held up.

The purchasing department can profitably study conditions and determine those items or materials that can be purchased to advantage in a finished or semi-finished condition. Savings are often made in this connection, as certain shops specialize in various lines and can produce them at figures lower than the average shop. Thus very considerable savings can be made by a live wide-awake purchasing department.

Overhead Expense

The overhead expense of any shop is always its own special problem. The item is the pooled expense of doing business, outside of the direct charges for material and labor. It covers the entire office expense, expense of administration, expense of supervision, cost of supplies, power, insurance, taxes of all descriptions, heating, drawing, designing, engineering service, experimental and development work, spoiled work, lighting, repairs, bad debts, interest on bank loans, interest on investment, depreciation of plant and equipment, funds for extension, liability in case of accidents, donations and other charitable gifts, and other indirect expense incurred in continuing the business, including that of selling expense, advertising and traveling salesman expenses, which subject we plan to deal with separately, later in this article.

It is common practice to pool these expenses and reduce them to cost per man per hour. Sometimes they are expressed as a percentage of the prevaling hourly rate of a machinist. It is only a compromise, at best, to express them in either of the two above mentioned ways. Logically, it is not good judgment to charge a certain rate per hour for a man's time on a small shaper or lathe costing less than one thousand dollars, and then to apply the same rate to the man when he is working on a six thousand dollar milling machine, or to a man working on a twenty thousand dollar planer which consumes more than ten times the power required by either of the two first mentioned machines. If an overhead rate is expressed as a percentage of the hourly rate paid the machinist, it quite often runs to 100 per cent. of this figure, but naturally it cannot be hard and fast, as it costs less to do high class bench work than it does to do ordinary work on big, heavy, expensive, and power-consuming machines.

The secret in figuring overhead is for one to have an intimate knowledge of all the special conditions in hand, so as to include all tangible as well as indirect expenses, and in addition place in those funds to be devoted to "reserve" and "depreciation" amounts sufficient to cover all reasonable future requirements. It must not be lost sight of, that whether a wheel is turned or not, overhead expenses continue. Depreciation in an idle plant is sometimes larger than in a going concern, and is at all times a heavy expense.

Every time a jig or fixture is used, it costs money. It was an expense to procure that jig and a return on the investment must be obtained. It also costs money to house that jig and keep it available for use. In the case of delicate and very accurate jigs an upkeep cost must be reckoned with. In heavy rugged jigs and fixtures that resist wear, it usually is safe to assume that changes in design will limit its life, and therefore it must earn its keep over a definite, and not an indefinite, period, or else it will be a losing proposition.

Every type of machinery is subject to maintenance costs. These figures vary in different shops. Any shop that has been operating for more than a year can make very close estimates as to the amount of their probable maintenance costs for considerable periods in advance.

Study Depreciation Costs

Some standard machines, such as lathes, are assumed to have a life of ten years. Other machines, such as planers, are given twenty years. Every machine should be alloted a certain length of life and its depreciation figured accordingly. This length of life is not necessarily the period over which it can be counted upon to do good work, as some machines become out-of-date, and of correspondingly less value, long before they are worn out.

Supplies required by shops are an important item in the overhead. Oils, belts, small tools, jigs, fixtures, cutting compounds, tool steel, fuel, pattern lumber and expense, foundry expenses or costs of castings, are a few of the many items. The list of supplies varies with the product manufactured, and other special conditions. It is always important to keep records of the consumption of supplies, so that a proper

figure can be obtained, when it is necessary to have same for estimates on prospective work.

Heating costs should be figured on a yearly basis in order that the summer business may be made to help pay the heating costs in the winter.

It never does any harm for a shop owner to audit independently his own books at the end of the year, and ascertain for himself all the various direct and indirect items that enter into his gross operating expenses. He will get many new ideas of expenses that are somewhat obscure but are inseparable from any business venture. He will be able to visualize and put in effect many economies, and will have a broader understanding of the word "overhead." It has been found good practice to give foremen figures which show the consumption of supplies over a given period. Comparisons with former consumption figures will be interesting, and may be the means of effecting a saving on many items.

In the matter of estimating on prospective work, records showing past performances are of great value. Nevertheless, it is often a matter of a shopman's ability to size up the work and to take into consideration all the special factors, which bring forth intelligent and accurate estimates. Experience is the great teacher as all estimates are very complex problems. Estimated figures should always be compared with the actual, as many valuable pieces of data can be thus secured.

Experience is the best teacher when it is necessary to unravel the problems that go to make up the elusive overhead.

Selling Costs

The last item of costs that must be charged up to an article is that amount which is required to place it in the hands of the consumer. To this account must be charged all costs of advertising, salaries and transportation charges of traveling salesmen, catalogues, sales pamphlets and other literature, expenses of crating, boxing, and packing, carting and loading expenses, and other items that are incurred in each individual sale. To add to this, is the cost incurred in some of the above connections where an unsuccessful attempt to close a sale has been made. Profits from actual sales have, of course, to take care for these indirect and unfortunate expenses. Branch offices, commission to agents, are all charges against the sales account. Many of the above items are in a class, which to a greater or less extent, can be controlled. Thus the executives of each individual shop must consider their own problems on their respective merits. If these expenses are recorded in such a manner that business can be traced more or less directly to them, the amounts that can be reasonably spent in the various ways, can be determined more or less intelligently.

A careless salesman whose actions tend to displease regular or prospective customers, is a source of expense, as he does great damage to the very valuable asset known as "goodwill."

In the case of firms whose product is exported, this end of the sales problem becomes a very complex one and it is not proposed to deal with it in this article.

Factors Making for Cost

Perhaps a few hints suggesting some of the obscure items of expense would be in order. Goods that arrive in damaged condition, and which are later the cause of claims or other troubles due to adjusting, etc., add to the cost of manufactured articles. Similarly outgoing goods that are badly packed are often the cause of direct expense to the firm shipping, and also the cause of the indirect expense of a dissatisfied customer. When shop routine is held up through the lack of small but important items, there is a tendency to cover up the matter, and it is not always brought to the attention of the proper executive. Guaranteed deliveries are sometimes an item of increased cost. A shop often gets behind schedule and overtime must be resorted to, in order to make promised deliveries. This factor adds to the cost of labor and other items.

A factor that is sometimes serious, and often an indirect loss, is for a firm to allow its accounts payable to become so large that is cramped for working capital. This means that extra cost is involved in the securing of money with which to operate, from the banks or other sources. In such cases opportunities to purchase advantageously are often allowed to pass. In dull times men are kept on the payroll for long periods when it is well understood that they have no opportunity of earning their money. These items have to be all paid for if a shop is to continue in business. Some plants fail to take advantage of side lines or fillers, or to reclaim scrap material. Such practices may only net nominal sums, but these amounts are very nearly one hundred per cent. profit. Some firms have a heavy burden to carry in the form of executives' salaries. Thus one may continue on down the line almost indefinitely.

The Proper Care of Belts

By J. H. WALKER

Managing Director of The Dominion Belting Co., Hamilton, Canada.

THERE ARE very few users of belts who give them the proper care. In the first place, they should be put on with clamps, or other means adopted, to take all the stretch possible out before lacing or attaching with other fasteners.

Every belt should have a proper dressing applied occasionally to keep it in condition. By this means drying out is prevented, and belts retain their gripping qualities on pulleys, which means a retention of the original power transmission.

A belt dressing containing resin or mineral oils should not be used, as these ingredients are most detrimental. Never use a belt dressing containing animal oils on rubber, balata, or stitched cotton duck belting.

The proper time to apply belt dressing is when the plant is closed down for a day or so; for instance, Saturday, as by Monday morning it has had a chance to penetrate the belt and keep it soft and pliable.

If kept in this condition there is no excuse for anyone resorting to the questionable remedy of applying resin, or any sticky dressing to get the proper power out of belts.

Belts used in saw mills and other plants that are shut down during the winter months should be taken off, rolled up, and kept in a warm place. If left on the pulleys and exposed to the changeable atmospheric conditions of a Canadian winter they will certainly have deteriorated by the spring.

Carelessness in starting up machinery too quickly is liable to cause belts to slip on pulleys, thus injuring them. This can be obviated by putting on the power gradually, which gives belts a chance to get a grip on the pulleys.

Another important matter is to have proper alignment of pulleys, as many belts give out before their time owing to defects in this respect.

Another mistake made by some belting users is practising false economy in getting belts too light for the work they have to do. While a certain weight of belt may at first do the work required, if it is necessary to keep it on a constant strain to accomplish this, both belt and machinery are going to wear out much faster than if there is a "reserve." In other words, heavy enough belts should be used to ensure their not being overstrained. This may cost a little more at first, but pays in the long run.

Correct Lighting Dependent on Proper Diffusion

Getting the Most From Natural Daylight—Modern Plants Constructed With That Object in View—Coating Walls With Light-Reflecting Colors—Better Lighting Systems

THE first part of this article appeared in the June 15 issue and brought out the point that due to the large number of mill whites on the market, it is often confusing to one not familiar with paint values, to determine just which particular coating is best suited to one's needs.

Price cannot always be used as a criterion, because the cheapest paint may not produce anything like the results anticipated. Even such a test as whiteness does not mean much because permanence of whiteness is just as important. There are other qualities too, such as opaqueness or masking value of the paint, and the ease of brushing which affect the quantity of paint and the labor cost of application. A mill white which covers much better than another and which is brushed out easier, may cost less in the end in actual dollars and cents expended for painting than another material that was originally quoted at an extremely low price.

In view of these facts, it was suggested that probably the best plan the average building owner, factory superintendent or maintenance engineer could follow, would be based on a competitive test carried on by such building owner's or maintenance engineer's own men, in his own plant, where all the determining factors could be taken into consideration and correctly estimated before coming to a decision.

Method of Procedure

For this purpose, it was suggested that an adequate sample—one gallon, five gallons or ten gallons (depending on the extent of the job) be ordered from each maufacturer whose mill white was worthy of consideration. No paint manufacturer has any objection to such a test being made in connection with his material as long as he is assured that the test will be unquestionably fair to his material and that his representative be given every opportunity to observe results along with the building owner's own men. The cans of mill white when received should be marked with a code number, preferably stamped into the metal, and the labels carefully removed, the code number being retained by one person only—the superintendent, factory manager, or other individual in charge of the test—and the unlabelled cans, free from any distinguishing mark, save the code be turned over to the painter for inspection and test.

The painter should be given instructions to coat two panels of the same size, of each manufacturer's product, two coats, on the same character and color of wood surface. All materials should be applied alike, and under the same conditions. These panels, when thoroughly dry, should be coded with the number of the paint used, and then put away in a dark closet, or in the drawer of a desk, or some other such place where no light can reach them. This is the best test of the non-yellowing qualities of white paint, because the average white paint, when isolated from daylight, has a tendency to yellow or turn dark. By placing these panels in a very dark environment, this tendency to yellow can be accelerated, enabling the test to prove out in from two to four weeks.

This will take care of permanence of whiteness. Incidentally, it will also give an idea of the comparative whiteness of one material with another, though a better test of this can be formed by the following: The superintendent or factory manager should then select a wall space in his factory, dividing this space off into equal sections. All samples should be tested in the same section of the factory and on the same wall, and subjected to the same lighting conditions, if possible, so as to have the test fair, and on a uniform basis.

Covering Capacity

The painter should now carefully measure a quart, half-gallon, a gallon or whatever quantity of paint he is going to apply, and brush this in the first section, marking the section with the code number of the paint used. The paint should be applied in this section until every drop in the can is used up. The next brand of material should be brushed out likewise in the next section, and so on down the line.

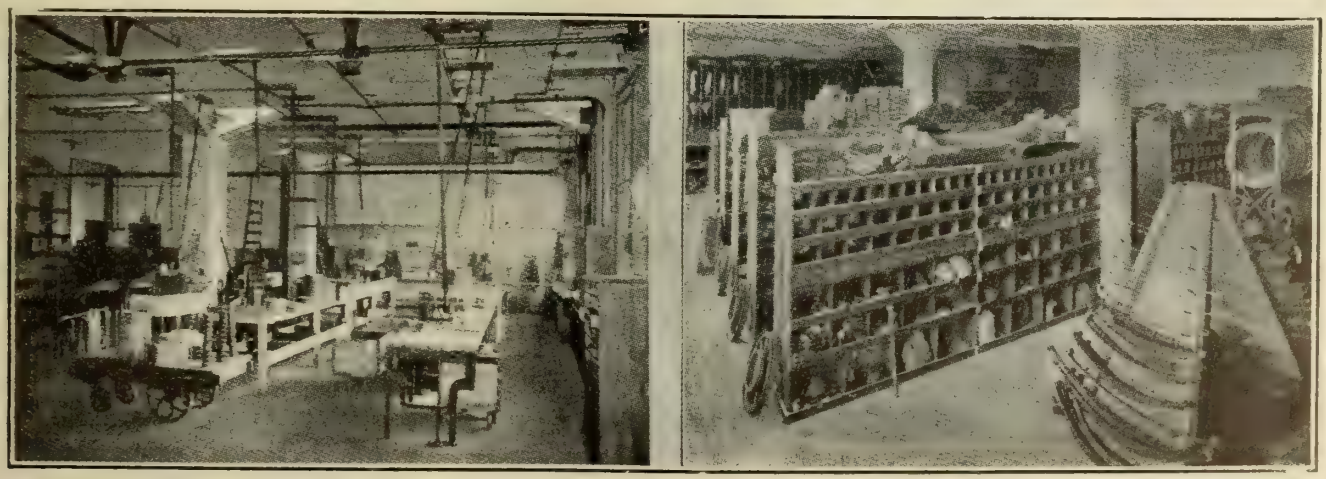
It will immediately be observed that some paints will "go farther" than others—cover more surface. If this test is carried out carefully, and the surface is of the right kind, so that all brands of paint are spread over a surface of equal and similar porosity, it will give a very excellent idea of the comparative covering capacity of the various paints.

The mistake should not be made of applying one material over brick, another over cement wash and a third over concrete. These surfaces all vary in their absorptive qualities, which is unfair to the paints. (The absorptive character even of different sections of the same concrete wall may vary, though this of course is a matter difficult to regulate). Following the application of the first coat, a second coat should be applied, having allowed 24 to 36 hours for drying. From these samples, if they are all painted on surfaces of the same density, shading and physical appearance, and exposed to an equal quantity of light, one can very readily determine which is the whitest.

The covering capacity can very readily be measured, while the opaqueness

---

Extract from an article in Building Maintenance issued by the Truscon Laboratories.



Left:—Showing well-lighted shop. Right:—Every bin and corner well lighted.

or "masking value" is something that should be determined after both the first coat and the second coat. It is entirely a matter of paint judgment, and probably the factory manager should rely on his painter to tell him which material, in his opinion, has the greatest opacity and body to mask the surface.

The ease of brushing is another point which the painter can best determine for himself. Ease of brushing is exceedingly important, because on this feature depends the labor cost of applying the paint. If a man who is paid 70c an hour can brush out 1,200 square feet of surface with one paint, whereas he can brush out only 750 with another, in the same length of time, it is obvious that the second material is costing more to apply than the first—a factor to be taken into consideration in the total cost of painting.

Figuring Different Values

By giving certain values to the various factors of the test it can be readily determined what the relative qualities of the different paints may be. As shown in Fig. 3, there are nine samples applied to the wall, numbered 1, 2, 3, 4, 5, etc., respectively. After careful consideration No. 4 let us say seems to be the whitest. We will give this a value of 20 and judge the other paints 10, 15, 18, or similar figures, depending on the estimated degree of whiteness that these fall short of No. 4. If No. 3, however, gives best results under the permanence of whiteness test, then No. 3 is given a rating of 20 for this classification, and all others graded accordingly.

By summing the numerical values of each of the paints applied, the building owner or factory superintendent is able to obtain a fairly accurate estimate of the true value of the various products as light-reflecting paints. The value of this method of testing is due to the fact that it is not based on one point of advantage alone, but it endeavors to take what experience has proved to be the five most important points, into consideration. If the plant superintendent or maintenance engineer will follow this system and compare his results with the prices at which the various goods are offered, he will find that he has arrived at a safe basis on which to make his decision.

Aspects of Lighting

The eye is an organ, which, like all other human organs, has a tendency to adjust itself automatically to new conditions. It does this often without our having any direct consciousness of the fact. Thus, for instance, in a room painted all white there may probably be too much light or more light than the eye is accustomed to receive. Insensibly it adjusts itself to this new condition, even without the worker's knowledge. But the adjustment is not a remedy—it is only a temporary relief, and if the work is persisted in, may eventually result in eye strain with its various eye diseases.

Shadows Often Helpful

The explanation of all this is of course that we see objects not only by the light that they reflect, but also by their shadows. Take as an example the cubes shown in Fig. 4. The cube in the center is so well lighted from all sides that it is difficult to distinguish its various surfaces. There is no shadow. The cube at the right has shadow but too much shadow on top. The cube at the left is correctly lighted, so that its shape, form and contour are perfectly distinguishable. This fact is taken advantage of in some shops by painting not only the walls and ceilings white, but also the work benches and machinery.

It seems apparent that when conditions dictate the use of a colored dado one should aim to keep away from black and red. Green probably is the best color, since it is the one color to which our eyes are by nature already accustomed. Green may not always fit in with the general harmony or decorative scheme of the building interior—but when bright reds or deep blacks are used they should be used with other colors.

Nevertheless in a type of manufacturing plant that requires the use of a dado, if the ceilings are coated with blue ribbon eggshell white, and the walls and columns down to a point about the eye level with the same color, and all else below that with a quiet, cheerful green, much can be accomplished, not only in good lighting, but in relieving eye-strain. A black line about an inch or inch and a half in width, used at the exact point of meeting beween white and green, adds somewhat to eye-restfulness, since it makes a line of definite demarcation between the two colors.

Summary

To summarize the entire story, interiors of buildings should be decorated, coated and otherwise finished so as to obtain the maximum benefit and good out of both artificial and natural lighting. The advantages of good lighting are as follows: 1. Economy of electric installation. 2. Economy of electric maintenance. 3. Economy of electric current consumption. 4. Less eye strain. 5. Cuts down spoilage. 6. Reduces accidents. 7. Increases accuracy of work. 8. Makes possible more work at less cost. 9. Easier supervision. 10 Clean and sanitary. 11. Favorable appearance.

Having once decided that it is possible to increase the lighting efficiency of the interior of the building, the next step is to get in touch with illuminating engineers, who from their experience in such matters, can advise the factory manager or maintenance engineer on just what his requirements are, how they can best be taken care of and the cost.

MOTOR CAR EXPORTS CONTINUE HEAVY

Speaking of Canadian activities of the motor industry recently, Pierre du Pont, president of the General Motors Corp., made some optimistic comments on present and future prospects. He stated that "The corporation is developing in its Canadian plant a line of export models which meet the requirements of foreign countries in the matter of taxation, fuel consumption, weight, tire milage and economical upkeep, which are major considerations in influencing the purchase of American products in foreign countries. The export business of the corporation is running three times what it was forecast six months ago.

Labor Demand Reflects Industrial Activity

Railway Contractors Finding it Necessary to Increase Minimum to 30 Cents—Welland Canal Operations Likely to Absorb 3,000 Men—Motor Industry Easing Off After Good Season—Planning Extensions—Number of Placements by Labor Service Greatly in Excess of Last Year.

THE EMPLOYMENT situation continues to show the effect of seasonal activities on municipal, railway and public works. The fact that Welland Canal contractors will require some 3,000 men, and that the rate of wage indicated for laborers is 35 cents an hour, has caused some stiffening of the wage offered for railway work. This, as previously announced in this paper, has been from 25 to 30 cents. So much work is available, however, at higher levels, that railway contractors have been forced to move the minimum up to 30 cents. The employment service in Toronto, reports that they have had many calls for men which they have filled at 30 cents, but complaints reached them that the men either did not reach their destinations or remained on the jobs but a short time owing to better prices elsewhere. With the Toronto Transportation Commission paying from 40 to 50 cents an hour the average for city labor tends upwards. So far as machinists or skilled labor of that kind, are concerned, very little demand is reported. Some manufacturers are taking on more men, temporarily at least, but this is not absorbing the unemployed in this department, and these men are trying out something else for the time being.

Between Season in Motors

The motor car industry, during its period of activity, took on fairly large forces of skilled mechanics, but there are indications that now that the between season is approaching, there will be some lay offs. One firm stated that they were running along nicely on present season orders, but that, having loaded up with skilled mechanics, were proceeding to weed out. They gave their best wage rate as 75 to 80 cents an hour. Another concern stated that with the completion of one or two large contracts the off-season was in sight, and they were laying off men for five or six weeks, in which time they expected the advance business for next season would have developed sufficiently to fill up their ranks again. They were paying 60 and 65 cents an hour. The motor industry seems to have found its stride and has had a prosperous season. One indication of this in the Canadian field is the fact that the Russell Motor Car Co., have renewed payment on their common stock. This had been passed during the first quarter. Still more significant is the plan of the Ford Co., to make huge extensions to plant at Ford. Ont. This company has just declared a dividend of 15 per cent. The Durant people are also planning new buildings. These will give a floor space of 400,000 square feet, or five times the present area. The production of a car to compete with the Ford is proposed, and the extensions will provide for an output of 18,000 cars the first year. Of this number 10,000 will be for export. The industry as a whole is preparing for a record season in 1923.

There is a demand for farm labor. Parties of able-bodied men from the Old Country, arriving in the past few days, have been quickly absorbed. Farmers show a preference for this type of help as they take to farm life more readily and are more contented and more ambitious than are the habitues of a city, the majority of whom cannot live down what has been rather jocularly referred to as "the call of the wild," and in a little while float back to scenes of noise and bustle. Many farmers are signing desirable men up on yearly basis for $300 to $350 and found.

Increase in Placements

There is marked improvement in the showing of regular placements as between month of May, 1922 and the same month, 1921. For Ontario, there were placed in steady positions 12,116 while in 1921, the placements were 6,186. The Toronto figures are, May, 1922, 4,163; 1921, 1,897. Other provinces show similar gains. For Quebec, although the figures are much smaller than those of Ontario, statistics being from a limited range of cities, the placements were: May, 1922, 1,303; 1921, 974

At the close of May there was a 12 per cent. increase in employment in the iron and steel group, representing largely reaction from the temporary losses recorded by the railway car shops at the end of April during one of their recurrent shutdowns. During the latter part of May some of the car shops had closed down, but all were working again before the end of the month. In addition to this revival of activity, there was some expansion in practically every division of the industry, notably in rolling mills, shipbuilding and repairing, heating appliances, boilers, engines and tanks, iron pipe and small hardware. Improvement was indicated in all provinces, the additions to staffs in Ontario, however, exceeding those reported elsewhere. Statements were compiled from 734 concerns in the group with an aggregate working force of 109,329 persons, as compared with 97,299 in the preceding month, an increase of 12,030 This expansion caused the index number to equal that indicated for the corresponding period of last year, so that for the first time this year the situation did not compare unfavorably with that reported for the same month of 1921.

The level of unemployment as indicated by the manufacturers making returns at the close of May was higher than at any time since the end of March, 1921. The improvement since the preceding month was especially marked in iron and steel and lumber, the gains in the former indicating recovery from the shutdown in the railway car shops reported at the end of April. Sawmills were very much more active, causing practically all the gains in the lumber group. In addition, a distinctly favorable movement was evidenced in fish canning, pulp, paper, biscuit, rubber, glass, brick, cement, electric current, nickel, tin, and petroleum factories. The only noteworthy contractions occurred in the leather and textile groups, and, as mentioned before, these were largely of a seasonal character. Reports for the month under review were received from 4,169 manufacturers employing 411,936 workers, as compared with 386,728 on April 30, the difference representing a gain of 6.5 per cent. The tendency indicated at the end of May, 1921, was downward and employment was about 3 points lower than for the period under review.

Gains in Building Trades

Employment in the building trades, as indicated by the value of the building permits issued in 56 cities, showed another decided increase during May, the value rising from $14,082,170 in April to $17,765,326 during the month under review, an expansion of $3,683,156, or 26.2 per cent. The value of the building authorized during May, moreover, exceeded that reported for the corresponding month of last year by $4,363,161, or 32.6 per cent., the permits for May, 1921, having aggregated $13,402,165.

The volume of building contemplated in all provinces except New Brunswick, Manitoba and British Columbia, showed considerable gains during May, the increase of $1,343,883, or 51.3 per cent. in Quebec being the most noteworthy. The largest percentage gain occurred in Saskatchewan, where the permits, valued at $1,281,431, were 315 per cent. higher than for April. The declines in the provinces mentioned above were all slight, that of 14.4 per cent. in Manitoba being the most pronounced.

E. G. Koyle, formerly branch sales manager of the Refinite Co., Toronto, has been appointed to a similar position with the Canadian International Filter Co., Toronto.

Hints on Setting Up and Clamping Work on Planer

Efficiency of the Electric Drive—Increased Range of Open Side Planer—Development of Double Deck Platen—Multiple Tooling Speeds Up Production—Offset Table a New Feature

By H. ALTON

During the war, in the Canadian Pacific Railway Angus shops planers were used in place of bull-dozers for drawing brass cartridge cases. These references go to show how versatile the planer really is, and in the hands of an ingenious foreman should rarely be idle.

Electric Driven Planes

Up to the present we have only touched on belt driven planers. Of late years electric motor drive has become popular on the largest machines. The form of drive has been so successful on these large planers that it is almost universally adopted. The electric motor of today is a rugged machine and in itself is very reliable. The planer motors are, of course, reversible and often of the variable speed type. Some motors on planers are equipped with a more or less elaborate control board. The stroke is adjusted by dogs in much the same way as a belt-driven planer. The dogs, when functioning, operate an electric switch which reverses the direction of flow of the field current. Thus in bringing the sliding and revolving parts to a stop and reversing them regenerating effort is often obtained, tending to reduce the peak load. On large planers auxiliary dogs are often found, which, when required speed up the planer on the cutting stroke. This is done when there are places in the cutting stroke where the tool is cutting air. Then too, it is desirable to slow down the platen as a tool enters the cut. All these things can be accomplished by means of the auxiliary dogs.

Electric drive eliminates belt troubles and permits the machine to be stopped or started from various places. On large work of an uneven nature, the variable cutting speeds save time and money. A small motor on the standards is a great time saver in moving the cross rail. On the whole on large planers, the electric drive saves a great deal of the upkeep cost. There is a limit in sizes, however, below which it is probably not economical to go, and all small planers are belt driven.

Open Side Planers

One of the great friends-in-need in the contract shop is the open side planer. Work is handled on these machines the limit of which is only the size that can be passed through the doors of the establishment. Ingenious devices for supporting overhanging work are found in many shops. The principle of operation is identical with that of the double standard machine. The only difference in design is that the cross rail is of cantilever construction and is supported by the single post or standard.

It is not uncommon to see a planer of the double post design widened out to take in extra wide work. Some Canadian shops have done this to their decided advantage. In the works of one of the big tool manufacturers in Illinois a 48-inch planer has been widened out to 72-inches to take care of some of their own shop problems.

Double Deck Platen

Probably no apparently simple improvement in machine tool design of recent years is more important than that of the double decking of the planer platen. The top of the platen has the usual number of slots and holes. The latter only go through the top section of the platen. The bottom of the platen is solid and between the two a large space is cored out with large holes entering this chamber, at the sides of the platen. All chips that pass through the holes are held in the chamber until the operator has an opportunity of raking them out. When removing them, they are thrown clear of the tool and out on the floor. This design of platen renders it practically impossible to get chips and dirt into the driving gears.

Special Designs

There are some very successful planers on the market to-day that use the worm gear drive. Then a planer recently appeared on the market with a belt-and-pulley link in the gear train, reducing the speed. The manufacturers claim special merits for their respective designs which are, without doubt, all operating successfully.

In the final application of power to the platen the rack and pinion are the accepted standard. Usually platens are cast iron and in modern planers the racks are of steel. There is no more important point to look into than the method of attaching this steel rack to the platen. Cases where racks have become loose are uncommon but considerable damage was done in those few cases where they did work loose.

Multiple Tools and Production Set Up

We have considered various ways of using the single tool on the cross slide and now will dwell on the multiple tool machine. When designers figured they had reached, for the time being, at least, the ultimate in the productive ability of one tool they were able to increase the capacity of the planer for work by equipping it with side heads on standards. Then came the planer with two heads on the cross rail. Fig. 16 shows a large modern planer

Illustrations shown in Fig 16 by courtesy of Niles-Bement-Pond Co. Those in Figs. 17 and 18 through courtesy of Bett's Machine Co. Line drawings prepared by the author. First part of this article appeared in July 6 issue.

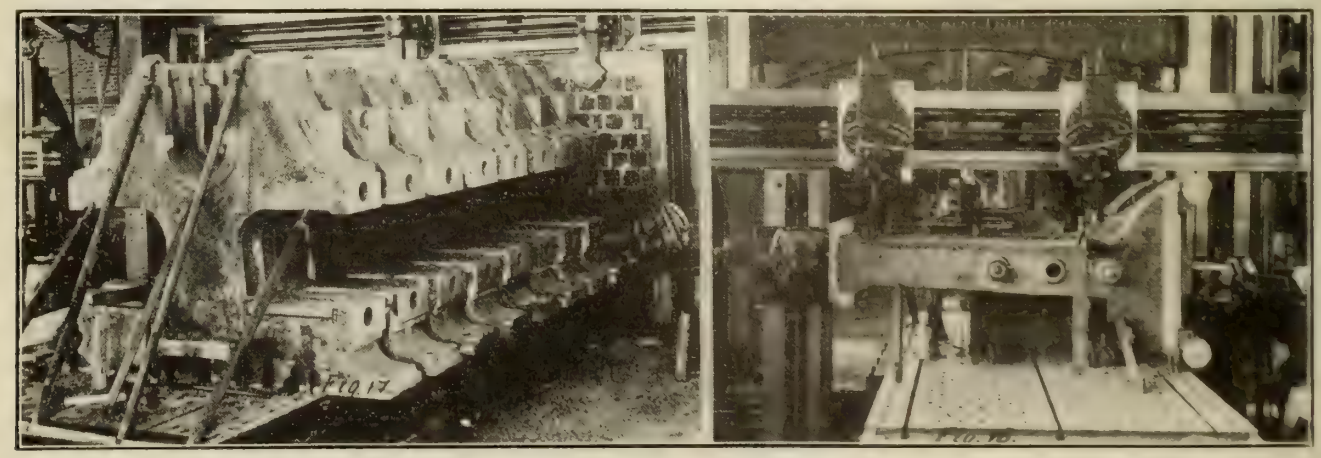

Fig. 17—Large planer with multiple heads machining housing casting for sugar machines. Fig. 18—Large planer with special patented sliding side head.

with three heads on the cross rail and one head on each of the two standards, making five in all. It will be noted that the planer is electric driven. There are several features of interest about this planer. Note the hand wheel construction for the vertical hand feed of the cross rail heads. The planer has one Vee way and one flat way. It is possible to use the five heads simultaneously, thus making intensive use of production time. Such practices, of course, materially enhance the ability of the planer to do work and increase correspondingly its earning power.

Fig. 17 shows a heavy duty planer 111 in. x 102 in. x 26 ft. planing length, built for machine shop in Alabama. The work shown on the table is a number of sugar mill housings having a combined weight of more than 64 tons. The planer is equipped with two cross rail heads and two side heads having power rapid traverse. All four heads are shown working on this job which in itself is a great saver of time. One of the cross-rail heads is extended down into the pocket at the top of the housings. The planer is driven by a reversing motor and the cutting speed is 30 ft. per min. with a return speed of approximately 75 ft. per min. The height from the table to the top of the housings is 90 in. and the crossrail is shown in its highest position with all four heads working. This method of handling eight housings in one set up where they formerly handled them one at a time is a great time saver and can be duplicated on other large and bulky work.

Best Design Metal Planing Machines

The common practice on metal planers is to mount the side heads on the face of the housing, arranging at the same time for a sliding movement for adjustment and feeds in both a vertical and lateral direction along these faces. In a good manw cases, and particularly on the smaller and lighter types of planers, this arrangement of mounting the side heads is very satisfactory. But there are many times, particularly on the larger and heavier machines, where the side head is too far away from the work for it to be used effectively on account of the lack of adequate support when the tool slide is extended.

The machine shown in Fig. 18 is one of the larger Betts planing machines of the new type which has a capacity of 13 ft. 2 in. between the housings, 8 ft. 2 in. under the cross rail and a planing length of 20 ft., which, of course, can be made any desired length. This machine is designed with a novel device, upon which a patent has been applied for, the purpose of which is to overcome the objection above referred to, as it enables the operator to adjust the side head close up to the work on the table as occasion requires and still have the advantage of a rigid support without excessive overhang of the tool slide. In other words, this design of planer gives the widest possible lateral movement to one or both of the side heads, retaining all the advantages of a wide planer with two uprights.

As will be noted in Fig. 18 the centre of the table is offset with the centre of the machine and the side head on the right hand housing will take care of the work without the necessity of extending the slide beyond a point where it does not receive proper support. The left hand side head is carried on a sliding base having its bearing at the top, on the under side of the cross rail, and at the bottom, on the foot of the upright. This base has a sliding fit on the underside of the cross rail and can quickly be moved in and out either by hand or by power. When it is in position it can be clamped to the cross rail as well as to the foot of the upright, on which it also has a wide bearing thereby making the whole construction practically one solid unit, and absolute alignment is assured at all times. It can be clearly seen that since this base, which is a steel casting, is held to the bottom of the cross rail, it will move up and down with the cross rail whenever the latter is adjusted for different heights, only requiring that the two clamps be loosened which clamp the base member against the foot of the housing.

When the base is fully extended it is flush with the side of the permanent upright and in this position the table will accommodate work the full width between housings, which in case of the photographs shown is 13 ft. - 2 in., when it is moved along to the right as far as it will go, it is right up against the side of the table. It is a very simple matter to move this base quickly by power from its extreme left hand position to its extreme right hand position. Both side heads are of course in line with rail heads so that no extra travel is required when taking cuts with rail heads and side heads at the same time which is a very important point on any planer having side heads.

Since this base which carries the side head has lateral movement which is easily controlled the operator can bring this tool right close up to the work without excessive overhang of the tool slide and thereby is enabled to take a much heavier cut than would otherwise be possible with overhanging tool slides. This construction can be applied to either the right or left hand side head or both as may be desired. All four heads are equipped with Betts patented feed and power rapid traverse arrangement. These feeds are entirely independent of each other in all directions. Thus the operator can take a cut with either one or both side heads while at the same time he can move the cross rail heads quickly along the cross rail by power rapid traverse or vice versa. The power rapid traverse to the heads as well as to the sliding base which carries the side head is operated through a double friction clutch by means of conveniently located gears, no shafts or idle gears are running when power rapid traverse is not used.

The same motor which raises and lowers the cross rail also furnishes power for quickly moving the heads, which as before stated can be applied to any one or more, while at the same time the others are used for regular feeding. The feed and power rapid traverse arrangement is absolutely fool proof. The table is of the original double plate box type construction, heavily ribbed, and is driven through all steel gears and steel rack. The driving power on this particular machine is furnished by a 75 h. p. reversing motor, giving cutting speeds of 20 to 40 feet and return speeds of 40 to 80 feet per minute. Forced feed lubrication is provided for the table tracks as well as for the driving gears and driving shaft bearings and the oil is filtered with a Bowser oil filter system.

The machine shown in Fig. 18 has the sliding base extended half way and is engaged in taking four cuts on a heavy steel casting used in connection with the manufacturer of steam hammers. It can be clearly seen that a heavy cut with the left hand side head supported in the usual way would be difficult if not impossible on a standard planer of equal size. This new type of planer will do practically all of the average work usually handled on an open side extension or convertible planer, and in addition it will handle the jobs more economically because all four cutting tools can be used to take heavy cuts. It has all the advantages of the open side planer combined with the well known rigidity and stiffness of the double housing planer.

Every additional piece of work that a planer will turn out represents not only a saving of interest of its cost but affects every item of shop expense. Therefore in the purchase of a planer, the first cost should not be the foremost consideration. The design of the tool in relation to the work to be accomplished should be carefully studied and a selection made only after a planer has measured up to certain specifications which govern good machine tool design.

Making the planer pay dividends, resolves itself to two special ideas. The first is to keep the planer busy by using it in quiet periods on a wide variety of work and the second is to keep as many heads as possible busy. A man in charge of a planer should never become imbued with the idea that it is only a necessary evil. The planer is a versatile machine. It is a precision machine, and intelligent thought given to planer problems will be found to pay good dividends on the time invested.

A Winnipeg despatch states that reports originating in strike circles across the line credit the railway shops in Winnipeg with making repairs on engines and rolling stock for American roads since the strike began. Officials there declare the rumors ridiculous. The Winnipeg shops are working full time preparing equipment to handle what is expected to be the biggest crop in the history of the west. They could not handle foreign rolling stock even if they desired or their men would consent.

Autobiography of Sixty-Four-Year-Old Engine

Born in 1858, Nine Years Before Birth of Dominion—Product of Dumfries Foundry—Cylinders Rebored Only Once in That Time —Still Going Strong With Chas. Barber & Sons, Meaford—Vertical Slide Valve Type—Has Passed Through Stirring Times

IT HAS often occurred to me that in any autobiography that I might be guilty of, it would be a difficult matter to establish certain matters pertaining to my birth. It seems reasonable to say that certain of the materials entering into my composition were originally in the shape of iron pigs, the ore from which came from a place I have often heard referred to as "the other side." Perhaps they brought my steel from the same place, but the fact that I wish to remember is that the castings, the pistons, the driving rods, and all that were turned out and assembled by the men of the Dumfries Foundry Co. in Galt in 1858. I understand that the firm has since changed its name to the Goldie & McCulloch Co.

It seems absurd that a steam engine such as I am should claim to be a member of any particular sex. If I were a female person, does it not seem ridiculous that I should boast about my 64 years of age? Moreover, in that time I have heard so many names applied to me that I confess I am a bit confused. I recall that, when they had me crated, and ready for shipment, one of the men came up to me with a brush and pot of glue and asked some person where "this bird" was going. The reply was that I was going to a village called Leith, near Meaford, and that it was a mighty good place to go. Let me whisper that my first job at turning the wheels of industry was in a brewery. But they fed me on steam from water, and, in spite of my surroundings, I never missed a stroke. Well, an engine must age quickly, in appearance, for I hadn't been on the job very long before the engineer referred to me as an "old girl." I took this in good part, but imagine my consternation when one day about 10 years ago a party of men looked me over and one of them referred to me as "some baby," while it wasn't so long after, that some youth with no germ of reverence in his soul, called me an "old coffee grinder." I think it was the boss who replied that "if you have done your work as well as she has by the time you are 60 years of age, you will not have to view the future with alarm." I thought that was rather fine, and I certainly delivered the goods that day, but there again he seemed to classify me as feminine.

So I have concluded that the sex of the steam engine. like that of a mud turtle or a concrete mixer, is largely a figure of speech. I just want to say that I have been wedded to work all of my life, that I feel fit as a fiddle yet, and if I couldn't do a good day's work I wouldn't want to be here.

To return to the story. A few years happened and I was moved to the machine shop of Chas. Barber at Meaford. Call it the irony of fate, or just engine luck, whatever you like, but to come from a brewery to a place where they were making water turbines seemed quite a radical change. However, I had always been noted for my sobriety, and I understand that, at the present time the national drink is water and quite a few places that once were breweries are specializing in what are known as kickless libations. I have often wondered how an engine would behave if given a shot or two of "double distilled damnation." I overheard a man remark once that he had had a few shots and felt all "gummed up"; so I supposed that would be my experience. Nothing, not even a human being, can do a good day's work as a regular thing, on gummed cylinders. Believe me or not, just as you like, but I should know what I am talking about when I say that in all my 64 years' experience, I have only had my cylinders rebored once, and that is the only time I was ever shut down for any length of time. That, I should say, is a record. I suppose there are those who will say that had I been fed on an alcoholic substance, my cylinders would have given out long ago. All I have to say is, it depends on the cylinders.

During my lifetime, a lot has happened to Canada. I had just taken on my first job at a time when there was some kind of row between Upper and Lower Canada over representation by population. In those days Upper Canada had about one million and a quarter of population while Lower Canada or Quebec, had about one million. Galt, I may say, had about 5,000. John A. was a prom-

Much Malingering Under Compensation Law

Board Reports Unusual Number of Complaints—Decisions Beyond Influence—Decrease in Accidents Due to Unemployment—Pensioners Seem Satisfied—Collective Liability System Working Well—Average Period of Widowhood About Three Years

CHARGES and complaints by employers of malingering and of employees being improperly kept upon compensation by doctors, under the Workmen's Compensation Act, have never been so frequent as at the present time. On the other hand, claims and applications for more compensation than is felt to be justified have never been so insistent. Even the good offices of persons supposed to have influence have at times been requisitioned, according to the 1921 report of the Compensation Board.

"Neither influence nor favoritism, pressure nor threats can be permitted to effect the broad decisions," the report continues, "any more than any of these things should be allowed to prevail with a court, a jury, or an arbitrator. Nor are they any more justifiable. It would be easier to grant requests which are not felt to be justified than to refuse them, but such a course would be a gross violation of duty and would soon bring discredit and disaster upon the operation of the act.

"Every care is used to avoid malingering, and as has often before been stated the board does not believe that malingering prevails to any serious extent. The accident frequency and the average time loss have varied but little since the act first came into operation."

Claims Decrease in Number

During the year the board paid out $6,189,263.49 in settlement of 45,191 accident claims. This shows a considerable decrease as compared with 1920 when compensations totaled $7,780,145.25 paid on 54,851 accidents. Fatal accidents numbered 386 in 1921 and 452 in 1920. This large sum meant an outlay of $20,637 per day, covered by 485 checks, while the reports of accidents averaged 151 daily.

The workmen's compensation act during its seven years of operation has dealt with 271,807 claims for which $27,947,653.45 was awarded in compensation and medical aid benefits. Employers pay the cost and the board merely distributes the money in a way that makes unnecessary all the claims for damages through the courts, which were so frequent in the old days. Now for every $100 of pay roll, the employer pays the board $1.12, and out of the huge sum of two and three-quarter billion dollars of pay roll in Ontario, industrial concerns have paid the province the money sufficient to meet nearly 28 millions in claims.

Those who benefit are not only the workmen crippled or injured in the industries covered by the act, but also widows, children and parents of workmen who have been killed.

The act, since it was first passed in 1914, has undergone a certain amount of evolution. Then the compensation provided for workmen was 55 per cent. of the loss of earning capacity, and for dependents a pension of $20 a month to the widow, with $5 a month for each child under 16. In 1919 these amounts were increased to $30 and $7.50 respectively, and to $40 for the widow and $10 for each child, in 1920. In the same year an amendment was added to cover the cost of all necessary medical aid as the result of an accident.

Simplifies Procedure

Distinguishing features of the act are collective liability of the employers in each class of industry, and simplicity and inexpensiveness of procedure. It differs from the old law which it superseded by covering all accidents arising out of and in the course of the employment instead of merely those which were caused by the negligence or breach of duty of the employer, and in substituting informal administration by a board for the technicality and stringency of court procedure. It differs from the compensation laws of most of the United States in making the employers in the various classes of industry collectively, and not individually, liable for payment of the benefits, though certain employers, such as railway and navigation companies, municipalities, etc., included in what is known as schedule 2, are upon the individual liability basis.

Regarding the system in operation, the report states: "The board feels there is no doubt as to the general superiority of the collective liability system. Individual liability, uninsured, would often ruin the employer and leave the crippled workman or his dependents without compensation. Individual liability, insured with private companies, is very much more expensive than collective liability administered as are the Ontario and other provincial acts. This is plain from a comparison of our rates with those of neighboring States. The reason is very pointedly shown in the last report of the Manitoba board, where the system was changed a year ago from individual liability with private insurance to collective liability. This report points out that under the former law 36 cents out of every dollar collected from the employer was allowed the insurance companies for expenses and profits. This was the percentage agreed upon between the companies and the board, after investigation, as being the proper and necessary allowance which the insurance companies should receive. In Ontario only two cents out of every dollar is absorbed in administration expenses. In other words, a dollar had to be collected in Manitoba to pay 64 cents in benefits, while in Ontario one dollar paid 98 cents in benefits. This means that if the system formerly prevailing in Manitoba were adopted Ontario employers would be paying $1.53 for every dollar of their present rate of assessment, or 53 per cent. more than they are now being charged. From 40 to 60 per cent. is in fact the percentage which it is usually admitted is added to the accident cost for the expenses and profits of private insurance"

An objection sometimes raised to the collective liability system was the possible lessening of incentive to accident prevention where the careless employer pays the same rate of assessment as the employer who takes precautions to avoid accidents. This objection had been met by a system of merit rating which has been in effect since 1917, under which as now applied a maximum difference of 55 per cent. of assessment is made between the employer with a good accident experience and the one with a bad experience, refunds up to 30 per cent. being made to the former and additional charges up to 25 per cent. levied upon the latter. Under this system $311,874.16 was refunded and $184,844.47 collected from employers for the year 1920.

There was also a provision in the act under which any employer who is flagrantly careless can be called upon to pay a special assessment, and this has been applied in a number of cases where such action was found to be warranted.

One of the reasons for the decrease in accidents in 1921 as compared with 1920 was the decrease in industrial activity and consequent unemployment.

For 1920 the average cost for each compensation case was $168.91 plus $26.28 in medical aid, as compared with $144.14 and $19.85, respectively in 1919.

For medical aid only cases $77,749.15, or an average of $5.00 for each case, was expended. In 1919 the average cost was $4.23.

There was spent for temporary disability $1,617,231.73, of which $1,184,660.92 was for compensation and $432,570.81 for medical aid. The average costs were $52.08 for compensation and $19.02 in medical aid, or a total of $71.10 for each case as compared with $55.01, of which $39.48 was for compensation

and $15.53 for medical aid, in 1919.

Permanent disabilities cost on the average $989.58, for which $189.39 was for compensation for temporary disability, $714.48 compensation for permanent disability, and $91.71 for medical aid. Comparable figures for 1919 are $128.74, $538.94 and $55.26, a total of $722.94 For compensation in permanent disability cases in 1920 there were expended $2,189,905.45 in compensation and $223,673.78 for medical aid.

On the average, deaths cost $3,778.89, of which $19.72 was compensation for temporary disability, $3,613.15 benefits to dependents, $96.25 for funeral expenses and $49.77 for medical aid. The total cost of deaths was $933,387.19, of which $291,094.06 was for compensation and funeral expenses and $12,293.13 was for medical aid. For 1919 cases, the average costs were: for compensation for temporary disability, $23.19; death benefits, $3,596.84; funeral expenses $72.50; and medical aid, $35.06; total, $3,727.59.

Great Variety of Causes

Mechanical causes were responsible for 12,881 cases, or 31.42 per cent. of cases, as compared with 32.75 per cent. in 1919, 35.92 per cent. in 1918, and 31.70 per cent. in 1917.

During 1920 there were 8,227 cuts, lacerations, and punctures, 5,459 bruises, contusions, and abrasions 2,561 crushing injuries, 1,856 fractures, 1,714 burns and scalds, 1,561 sprains, strains, twistings, and wrenchings, 775 eye injuries, 195 dislocations, 77 hernia, 56 cases of concussion, 10 cases of internal injuries, 10 industrial diseases, and 245 cases of other injuries causing temporary disabilities.

Of the 2,439 cases of permanent injury, there were 321 cases of disability exceeding ten per cent. of that earning capacity, as compared with 308 in 1919. There were altogether 151 cases of permanent injury to eyes. There were 15 cases of disfigurement, 1 case of loss of sense of smell, and 6 cases of impairment of hearing. There were 14 cases of permanent total disability, as compared with 12 in 1919 and 28 in 1918. These cases divide: loss of use of both hands, 1; loss of use of both legs, 2; loss of both legs, 1; loss of both eyes 2; paraplegia, 2; hemiplegia, 1; hypochondria, 1; mental confusion, 1; insanity, 2; general debility, 1.

There were no cases other than of temporary disability caused by industrial diseases in 1920. There were 10 cases, one each of anthrax and mercury poisoning, and, 8 cases of lead poisoning.

The board has made an exhaustive study of the separate cases in which pensions were awarded to the families of men who were killed in accidents.

In the 1,374 cases in which pensions were awarded there were 3,530 dependents. There were 1,187 widows, 2,117 children, of whom 64 were posthumous and 3 invalids over age 16, 123 mothers, 59 fathers, 7 grandchildren, 2 grandparents, 24 sisters, 9 brothers, 1 aunt, and 1 foster-mother of dependent children.

Statistics on Widowhood

Of the 1,187 widows drawing pensions in 1920, 168 have re-married. In these cases it was found that the average period of widowhood was 2.88 years. Fifteen re-married inside of a year, 35 during the second year, 55 during the third, 24 during the fourth, with a decrease each year to 7 in their seventh year of widowhood. The age of widows at the time of re-marriage shows the largest number, who gave up single blessedness was between the ages of 30 and 35, who numbered 47 as compared with 34 between 20 and 25, and 33 between the ages of 25 and 30.

That pensioners are satisfied with the workings of the board was revealed in the enquiry conducted to obtain various particulars regarding each case. On this point the report states:

"The pensioners were asked to state any complaint which they might have. Response was made in nearly every case. In seventy cases only out of 1,042 cases of pensions a complaint was made; in the other cases the pensioner replying either stated there was no complaint or made a commendatory statement; and in one hundred and sixty-eight cases failed to send in any response.

It is the policy of the board to encourage the "safety first" movement and a total of $46,696.23 was paid in 1921 to safety and accident prevention associations.

AUTOBIOGRAPHY OF ENGINE

(Continued from page 28)

inent Conservative in those days, while George Brown was one of the advocates of reform. Things were shaping towards Confederation and I was some engine on that 1st of July, 1867, our first Dominion Day. I remember the American Civil War, which Canadians helped to win, and also that first of June in 1866 when the Fenians crossed over at Black Rock near Buffalo and threatened to clean up Canada. However, I still plugged away, and was pleased to learn shortly afterwards that the Fenians had returned home, not without losses, and that these unfriendly acts were stopped.

Among other events of an unpleasant nature that have occurred in my day was the Red River rebellion in 1869, when Louis Reil, and some French and half-breeds on the Red River, resented the action of the government in taking over the Northwest. This trouble was crushed, and the country settled down to business. I want you to know that I was shaking a pretty mean piston when Winnipeg, then Fort Garry, was in the making. I was in fine shape during the building of the Intercolonial and the Canadian Pacific railways, and have passed through all kinds of those political crises which seem necessary in the building of a young country, and it is some source of satisfaction that the country and I have come through it unscathed and still have a future. I think it was during a political campaign that I was bored for the second time in my existence.

The Northwest rebellion came along in 1885, and was short-lived, as was also Louis Riel, once they nabbed him. Then fourteen years later, occurred the South African war, and Meaford sent some of her boys in the first contingent to aid the Motherland. Maybe I didn't regret that I was only a steam engine in those days, but I did the next best thing and kicked out a good day's work at home. Then, in 1901, the whole country mourned the death of Queen Victoria. It was not long after this that the Duke of Cornwall and York visited Canada.

You must remember that during all of these years, Canada has been growing by leaps and bounds, not only in population, but in development of resources. When I was but a kid, they still illuminated the streets with coal oil lamps, and the houses to. Horses were used for Toronto street cars. If a person wanted to go anywhere he probably went on horseback. It took three or four hours to drive over to Owen Sound, and here I want to say that I hope I'll live to see the day when there will be some kind of railroad running over to that town. To drive that distance in winter time is no joke. Well, now we have gas and electricity and these have brought about great changes in methods of doing things. To add to the pep of the times, along came the motor car, and the internal combustion engine and aeroplanes, all that sort of thing. Speed and increased production have supplanted the methods of saddle days. I want to claim a certain amount of credit, for I have had some share in it all, having helped turn out equipment used to generate electricity. Interesting, is it not, to think that an engine of my age should be identified actively in a modern engineering plant?

The most tremendous event of my career was the world war. This was a gigantic struggle, and early in the game I could see that it was going to demand the best in all of us. We were pushed to the limit, but again came through victorious. The fact I want to press home here is that a lot of things, some big and some little, some good and some bad, can happen in the course of sixty-four years, but if you are made of the right stuff, stick to business and measure up to its demands, you are bound to come through. Take it from one who knows more about revolutions than Ireland or Mexico put together, the man or engine who minds his own business, and does it well, won't have time to get into trouble.

There goes the whistle, and I guess they'll choke me off for the night. Take a look at my picture. I'm of the vertical, slide valve type, and differ somewhat from my more graceful, modern brothers or sisters. But though I may be odd looking, I know something about "the amplitude of time," and don't owe anybody anything.

Recent Developments in Mechanical World

The Metric System by Easy Stages

WITH THE object of accelerating the introduction of the international metric system, the Decimal Association of London, England, now recommends gradual modification of the existing Imperial system of weights and measures. For instance, states Hardware and Machinery, it is proposed that the existing table of avoirdupois weights would be greatly simplified and that closer co-ordination with the metric system could be secured by the present adoption of the following interim table: 7,000 new grains, 1 metric lb.; 16 new drams, 1 new oz.; 16 new oz., 1 metric lb.; 2,000 metric lb., 1 metric ton. The metric lb. and its parts would weigh about 10 per cent. more than the Imperial lb., and 2 such metric lbs. would be exactly equal to 1 kilogram. The suggested abandonment of all the present confusing intermediate denominations of weight between the pound and the ton simply follow the practice already successfully established in the United States of America, and also in some of the British colonies.

Unique British Hydro-Electric Installation

A WATER power station with some original and most interesting features has just been completed in Scotland. A small head of water had been used for a long time in driving two mills by old-fashioned breast wheels. Owing to the increasing demand for power, states a writer in Hardware and Machinery, the question of re-organizing the installation became pressing. It was eventually decided to use the water power for generating electricity, and to augment the supply of water power by arranging a high level reservoir into which water could be pumped during the hours when the mills were not working. Actually the mills work for about 50 hours per week. During these working hours the water runs down from the high level reservoir through the same pipe up which it had previously been forced, and it drives a Pelton wheel, which generates the additional power required. This plan has frequently been discussed by hydraulic engineers, especially in connection with tidal power.

Protecting Iron and Steel

RAPID PROGRESS has been made in acquiring that knowledge of the relation of pigments and finished paints to corrosion which is necessary to a better protection of iron and steel. Predictions founded on theory that a basic paint, or one containing a chromate pigment, would inhibit rusting, while one made up from lampblack or graphite would accelerate rusting, have, in the main, been found correct. The effect of the pigment upon the character of the oil film making up the paint, however, has shown itself also to be very important. Many basic pigments, says the Valve World, such as basic lead carbonate or zinc oxide which in themselves inhibit, do not withstand the weather; lampblack and graphite, on the other hand, make a very impervious and highly resistant paint film. The logical conclusion in protecting iron is, therefore, to use a basic pigment and a little lampblack, and when well dried out to apply a lampblack or graphite finishing coat. Experience has shown also the importance of brushing the paint well on to the iron; a good paint may fail on account of poor application.

French Railways Adopt Petrol Motors

FOR SOME time past, the French State Railways have been carrying on experiments to ascertain the possibility of using petrol-driven motor traction on lines on which traffic is limited. These trials have, states The Engineer, given very satisfactory results. A 60 hose-power motor weighing 14 tons and drawing a carriage weighing 10 tons easily reaches a speed of over 30 miles an hour, the speed being very slightly reduced when a second carriage is added. On local lines of normal gauge it is estimated that motor traction would enable a saving of from 5f. to 10f. per kilometre to be made, the present figures for steam traction being more than 14f. M. Le Trocquer, Minister of Public Works, who has been following the experiments with interest, considers that the results obtained are sufficciently satisfactory to warrant a circular to all Prefects of Departments, asking them to study the possibilities of applying traction by petrol motors to the departmental railways. Local railways have been much affected by the present high working expenses, which are not balanced by the increase in fares. It is estimated that the operating cost may be halved by the adoption of petrol-motor traction on many of the smaller local lines.

Life of Buried Steel Oil Tanks

SOME investigations carried out in America on the life of buried steel oil tanks, on behalf of insurance associations, showed that:—(1) Cinders stimulate corrosion probably because of the electrolytic action between the steel and the carbon in the cinders. (2) The best soil coverings given in order of protective quality are: oily sand, sand, gravel, clay, loam and cinders. (3) Red lead followed by asphalt gives the best results as protective covering. (4) Tide-water and ground water do not stimulate corrosion to any great extent. (5) If a tank is buried below the zone of active oxygen it is usually below the zone of corrosion. (6) Steel tanks buried under favorable conditions should last more than thirty years. In damp ground they will last from fifteen to twenty years, states The Engineer. To resist corrosion best steel tanks should be coated with red lead and asphalt and buried in clean sand 3ft. or more below the surface, avoiding ground water and tide water if possible.

Carrying Capacity of Bearings

EXPERIMENTS at the British Bureau of Standards determined the maximum safe load and static friction under loads of ball and flexible roller bearings. Tests were made on balls of 1.25in. and 1.50in. diameter in grooved races and on rollers 1.25in. in diameter and 5.25in. long in flat and cylindrical races. The total deformation and area of contact of bearings and races, says Practical Engineer, were measured and compared with Hertz's theory. The results agree roughly with Hertz's theory. The differences are ascribable to inhomogeneity of the material. The ratio of friction to load is practically constant and equal to 0.00055 for all three sizes of balls up to a "critical" load, which varies with the diameter of ball—1,300 lb. for 1.00in., 1,700 lb. for 1.25in., and 2,200 lb. for 1.5in. balls. A similar "critical" load, 25,000 lb., was found for the roller bearings with a ratio of friction to load equal to 0.00075. This "critical" load at which the friction began to increase more rapidly was in all cases lower than the safe load as determined by permanent deformation and as calculated from Stribeck's law.

Iron being the base of the mechanical, and sulphuric acid the base of the chemical arts, Ontario ore seems to be the answer.

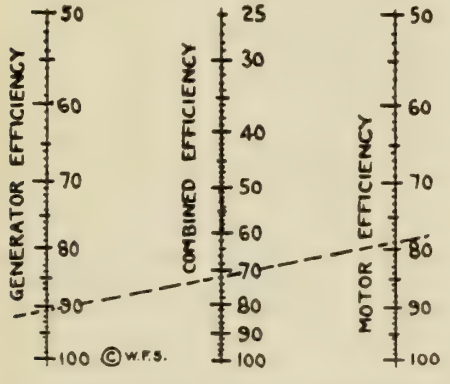
Practical Ideas From Practical Men

WHAT IS THE COMBINED EFFICIENCY?

By W. F. Schaphorst

In the electrical transmission of power we always have at least two efficiencies to consider—the efficiency of the generator and the efficiency of the motor. Where the distance between generator and motor is great the line efficiency also must be considered, but in most factories and shops using electric power distribution the line efficiency is so nearly 100 per cent. that it can be neglected. I have therefore neglected line efficiency on this little chart.

For example, if the efficiency of the generator is 91 per cent., and motor 79 per cent., the dotted line drawn across this chart shows the combined efficiency to be 72 per cent. The chart will figure



any combination where the efficiency of either generator or motor is over 50 per cent.

One of the much mooted questions is: which is best—electric or belt transmission? The answer is: "It all depends on conditions." The object of this chart, therefore, is to help you answer the question for yourself. With ball bearings and low belt tensions the efficiency of belts and shafts may reach a very high figure—95 per cent. and over. That is a point that must be taken up with the manufacturer. But if it is made certain belt transmission will provide even 80 per cent. efficiency that, in most cases, would eliminate the electric drive, although, of course, efficiency is not the only thing to be considered.

To assist users of the chart I give these average efficiencies of generators and motors at full load: Direct current generators—50 Kw, 90 per cent.; 100 Kw, 91 per cent:; 1,000 Kw, 93 per cent—Motors, ¾ h. p., 64 per cent.; 5 h. p. 80 per cent.; 15 h. p., 84 per cent.; 30 h. p., 90 per cent., 150 h. p., 92 per cent.

Alternating current generators: 50 Kva. 90 per cent.; 100 Kva, 91.5 per cent.; 500 Kva, 94.5 per cent.; 1,000 Kva, and over 95 per cent.—Motors, 1 h. p., 76 per cent.; 10 h. p., 85 per cent.; 100 h. p., 90 per cent.; 200 h. p., 92 per cent.

DIFFICULT PATTERN PROBLEM

By D. A. Hampson

Machine shops come in contact with architects but little, and vice versa, though occasionally a blue print from the building profession does find its way into our realm. It was in connection with the new bank building in town that we once more encountered an architect's design, this time as a request for a price on the part shown by Fig. 1.

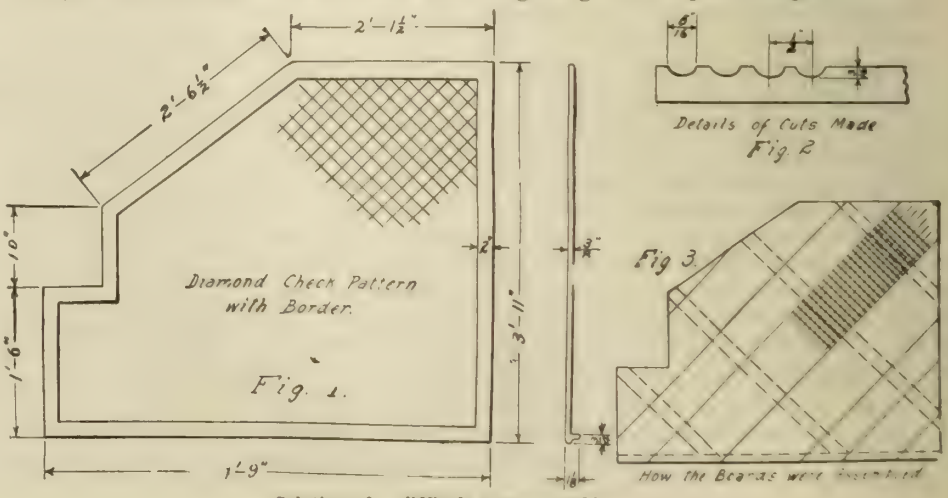
An examination of the drawing shows that it requires a pattern less than half an inch thick and roughly 47 in. x 57 in. Also that this area is covered with a series of diagonal grooves as shown at Fig. 2—over two hundred and fifty in all—which end in a plain border all around. Everyone familiar with the mechanical trades will say at once that such a design is ridiculous—that two pieces of steel corrugated floor plate could be welded together at a fraction of the cost of the pattern alone and be a better job, that the cost of making one such pattern for one casting is entirely out of proportion.

We knew all of this, and the more we studied the drawing the less we felt inclined to quote on the job. Those who have had experience with diagonal grooving jobs will agree with us that such work is the most deceiving of all the simple jobs that crop up, both as to speed and cost and to accuracy. To set a saw gauge at an angle, pass your boards over the saw, and expect your cuts to come out evenly spaced and parallel is a seeming impossibility. Even if you have a series of holes or slots for spacing and have the assistance of a second person to help keep the boards in place and to support these exasperatingly long overhanging ends, you have the same trouble.

In this case, we called up the builder and told him frankly that no engineer planned that piece, that it would cost the best part of fifty dollars to get out the pattern, and that we didn't want the job. He countered by saying that it would take too long to correspond with the architect in New York and for us to go ahead and make the piece as cheaply as possible. Well, when a disagreeable job is forced on you, you usually get it out of the way as soon as possible—and that's what happened to this stair casting.

The solution was so simple that it is ridiculous, yet in half a dozen cases of this kind, no one has thought of that way out. Fig. 3 shows how it is done. We had a grooving tool of the desired radius and, aside from that nothing but the cut-off and ripping gauges on the saw were used. One man did the work alone. A sufficient number of ⅜ in. boards were gotten out and jointed carefully on the edges. Then each board in turn was placed against the cut-off gauge and grooved across the grain, spacing by means of a latch dropped into a notched bar which was part of our regular pattern shop equipment. Next the boards were grooved lengthwise. This gave us the diamond check pattern required, but at an angle of 45 degrees to the outsides of the piece as detailed, which was easily remedied by the "solution" by cutting off the edges of the boards to the same angle.

Referring to Fig. 3, it will be seen that the diamond effect is obtainable this way and that by placing battens, as indicated by dotted lines, the assembly was made reasonably secure. The molding rib along one edge, also helped to stiffen. Thus a fairly good pattern was made up for about half what we thought possible. The boards were grooved clear to the ends and the plain border was obtained in the foundry by the molders measuring off a two-inch strip and sweeping away the impression of the grooves from there to the edges. The casting came out well and we felt that we had contributed much toward making "a go" of a poor design.



Solution of a difficult pattern problem

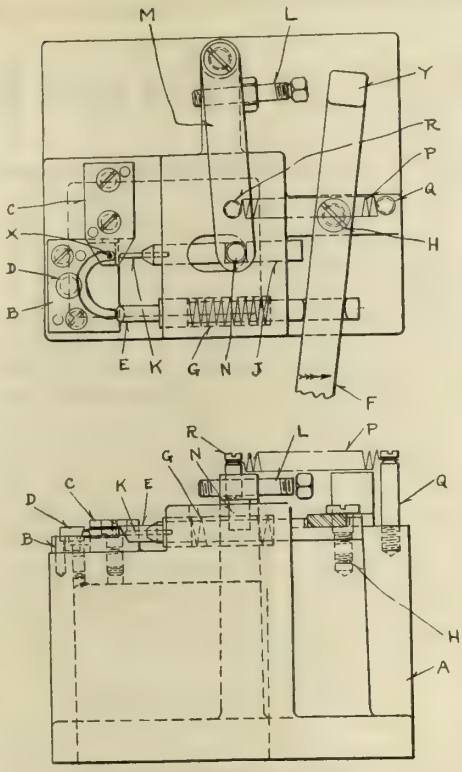
A LEVER OPERATED DRILL JIG

By F. Scriber

For the speedy manipulation of parts to be machined and for handling clamping members the operative mechanism used in the drill jig shown by the accompanying illustration provides a striking example of plunger and lever arrangement for both the holding while drilling and the ejection following the drilling of small work. This shows one operative lever only for performing both the clamping and removing of the part being machined this lever being used to operate all of the attendant mechanism, the various units being as follows.

The base of the jig is indicated as A and this is made of cast iron. Held to the upper side of this by screws and dowels is a hardened steel block B which is grooved out to locate the work; a block C is likewise held to the upper side of A this being used to locate the work radially and also to hold down the end of the work where drilled at X. This block is machined out to suit the work and also to act as a stop for the same. At D a pin is provided which is grooved to fit the contour of the work, while a plunger E having a beveled end which comes in contact with the work holds down the same and pushes it against the stop at X. To operate this plunger E a lever F is provided which enters a notch cut in the plunger. This lever is used to pull back the plunger as a spring G pushes it forward to its clamping position. This lever pivots on stud H. At J another plunger is provided in the end of which is a pin K, the object being to strike the end of the work when lever F is pushed in the direction of the arrow. The end Y of the lever strikes screw L held in short lever M, in the end of which is a pin N passing through an elongated slot in the casting and entering a slot cut in the plunger J. These parts, with the exeception of the spring P attached to pins Q and R for pulling back this ejecting arrangement, completes the construction of this drill jig.

In using this tool an operator puts the work in the groove of block B as



Lever operated drill jig.

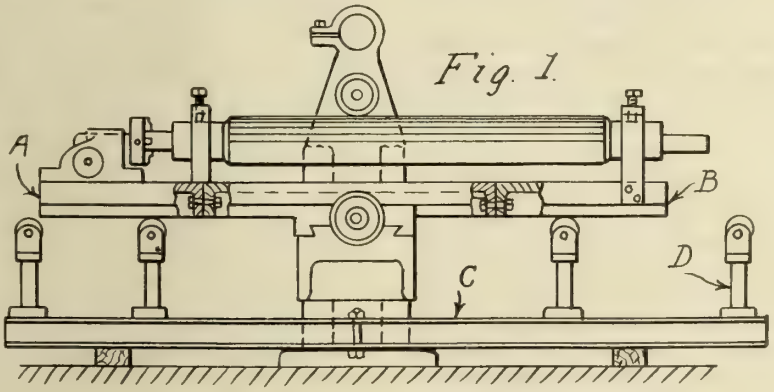
shown, at the same time holding back lever F and in turn spring pin E. When lever F is released the spring securely holds the work in place and requires but a few seconds of time to handle. Upon the completion of the drilling operation the act of pushing back lever F causes the plunger K to strike the work, thus knocking it out of place with a circular movement, permitting it to be readily pushed to one side by hand for the insertion of another part. The simple completeness of this drill jig and features of construction are of such a nature that they readily suggest themselves for use in tools for quantity production.

EXTENSION TO MILLING MACHINE TABLE

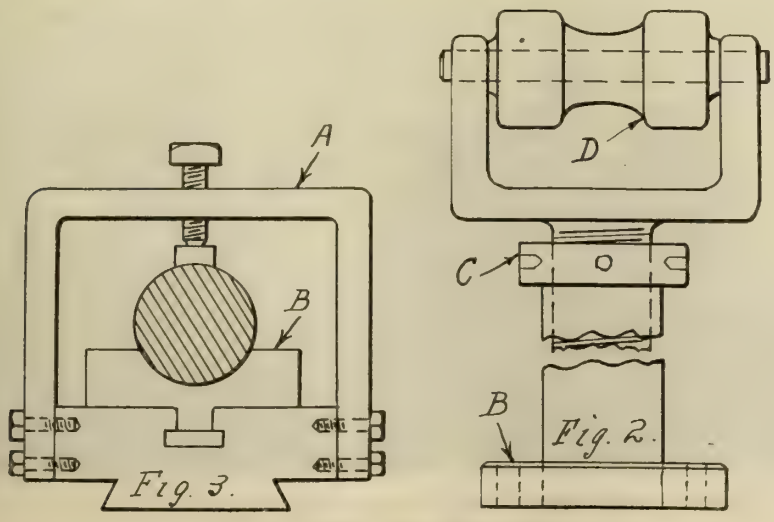
By Geo. Barrett

In most machine shops, where special machinery is made, the foreman is frequently required to provide ways and means of producing the work with the limited equipment in his shop. The sketch Fig. 1 shows the extension to a milling machine table, which was designed in order to mill the corrugations in large paper mill rolls. These rolls were previously imported from the States and the saving in cost of transportation, duty and exchange more than paid for the expenditure for the attachment here shown.

This consists of two additional lengths A and B fixed to the ends of the table proper. There is also a six-inch I-beam C, which is bolted to the base of the machine to carry four supporting rollers D. These are shown in detail in Fig. 2, the column A being made of 3 in.



Extension to milling machine table.



Details of table and work supports.

iron pipe and screwed into flange B. The vertical adjustment is made by the rotation of the ring nut C, which raises or lowers D to desired position. The massive weight of these rollers would not permit them to be carried on the centres of the dividing head, so this difficulty was overcome by making a special rest D, Fig. 1. This rest consists of a machine steel strap which is bent to the width of the table and bolted to same on either side. The main member B is made of cast iron, machined all over, having a tongue on bottom to fit slot in table, the circle being laid off and bored to suit the required height of dividing head centre. These rollers call for great accuracy on account of working in pairs and if one is out of true it would cause and paper to tear. The fixture described has been used on quite a number of rolls with good results.

New Things in Shop Equipment

REGRINDING MACHINE

An 18 x 72-in. autopart regrinding machine that has a greater capacity than previous ones of the same make has recently been placed on the market. Power-driven table traverse is provided, and the machine can be operated by belt from line shaft or from a motor located at rear of machine. It can be readily adapted to all classes of cylindrical grinding. The general dimensions are similar to those of the 18 x 55-inch machine made by the Norton Co. of Worcester, Mass.

PLAIN CYLINDRICAL GRINDER

A recent addition to the Norton line of grinding machines is one that has been developed to meet the demand for high production but occupying less space than the 10 in. machine, by shortening the distance between work centres. The latest grinder has a centre distance of 18 inches, as it was felt that this would accommodate a very large group of parts to be ground, particularly parts produced by automobile companies, and accessory makers. This machine is manufactured by the Norton Co. of Worcester, Mass.

SURFACE GRINDING MACHINE

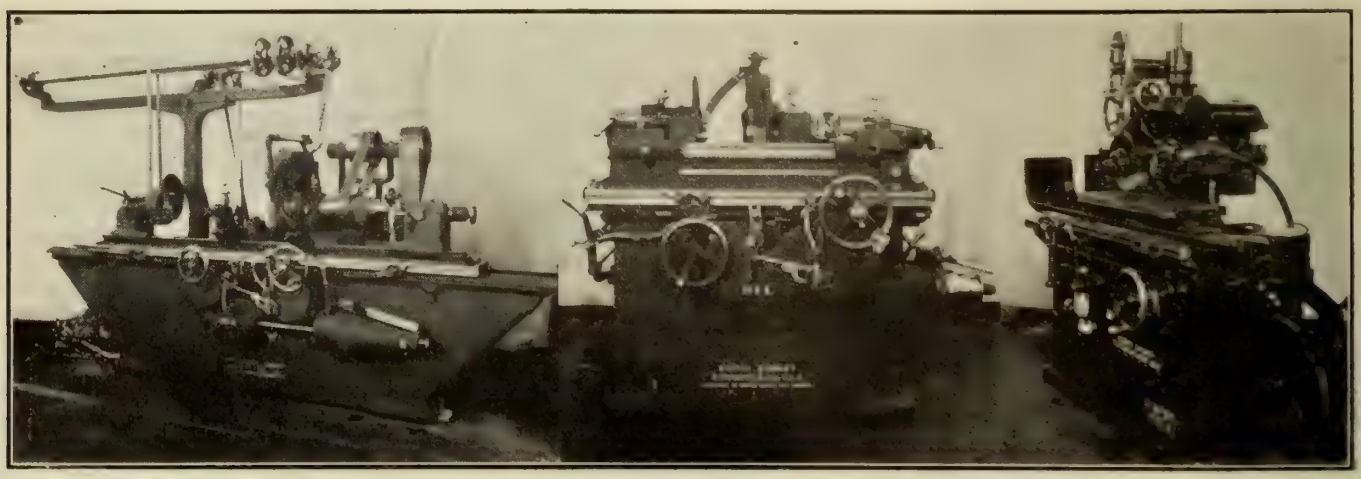
A new design of precision surface grinder intended for high production work, has just been offered to the trade. The table surface has an area of 36 in. x 6 in. and has a capacity of work to a width of 8½ in. The clearance between 10 in. wheel and tables is 10¼ in. A notable feature of the machine is the improved spindle construction. This consists of thumb screw adjustment for both end and radial thrust and flood lubrication. The thrust is taken by hardened steel flange running between bronze washers. The wheel spindle operates at 1,342 r. p. m. and is driven by a 4 in. belt. A 15 h. p. motor is belt connected to the main drive shaft which runs at 815 r.p.m.. Table travels at a speed of 80½ ft. per min. The hand traverse mechanism engaging automatically when the power traverse is disengaged. Power operated vertical feed can be given to the wheel, each graduation on the index wheel representing a movement of 0.00025 in. A portable tank is provided for the cutting lubricant, and this tank can easily be removed and cleaned without interrupting the operation of the machine. The machine weighs about 6,500 pounds and occupies a floor space of 10 ft. 8 in. by 5 ft. 3 in. This grinder is manufactured by the Norton Co. of Worcester, Mass.

INSIDE MICROMETER

A new low range inside micrometer has recently been developed and placed on the market. This micrometer, graduated to read thousandths of an inch, has the usual half-inch run of spindle with a measuring range from 2 in. to 32 in. It embodies the unique sturdiness of the previous style of micrometer of this make and retains the regulation diameter of barrel, spindle and thimble the extra large surfaces allowing for figures of generous size. The rods, fitted with hardened tool steel anvils adjustable for wear, are interchangeable on the threaded stud at end of micrometer head and can be used in combination. A detachable handle is furnished and so arranged that the micrometer can be used for right or left-handed work, a feature peculiar to this tool. The standard set packed in a pocket-size case consists of the micrometer head and adjusting wrench, five rods and one half-inch spacer, the capacity afforded being 2 to 7 inches. When five additional 5-inch spacers are used the maximum range of 32 in. is secured. Thus the tool is capable of gaging the smallest automobile cylinder and will take care of the larger measurements in shop use.

The inside micrometer can be quickly transformed into a height gage by use of height gage attachments. By attaching a rod of proper length to the micrometer any desired range from 3 in. to 32in. can be obtained. The rod is inserted downward through the steel case-hardened base until the anvil finds the surface from which measurement is to be taken. A quick-clamping knurled nut easily operated by the fingers, firmly holds the measuring rod in a perpendicular position. Such a tool is useful in obtaining the height of projections from plane surfaces, the location of bushings in jigs, etc. It is particularly convenient on planer work which often requires measurements to be taken from the bottom of a groove to points above and for setting planer tool or the milling machine table. The V-shaped groove in the bottom of the base adapts the tool for use in cylindrical works, measuring distances between shafts for alignment purposes, etc. By inserting a .250 inch drill rod in the base and attaching any standard indicator, a surface gage is in readiness for use in straightening shafts so for checking variance in distance between surfaces. A surface gage scriber can be easily clamped to the rod, forming another handy tool.

This differs from the height gage-alignment attachment No. 6 in construction and is intended mainly for height gage purposes. Having a larger base area than similar low-priced attachments, greater stability is insured. The reamed hole, which fits the sturdy measuring rod to a nicety, is also greater in size and depth. The upper end of support, vertically split at right angles, is adjusted to afford a sliding friction as the rod is inserted and will tend to



Left: Regrinding machine. Centre: Plain cylindrical grinder. Right: Precision surface grinding machine.

prevent side play, should wear take place from constant use. It also holds the base and micrometer measuring rod intact when the tool is lifted from one surface to another, while its knurled exterior is convenient in handling. These tools and attachments are manufactured by the Reed Small Tool Works, Worcester, Mass.

SLOW SPEED DRIVE FOR BORING MILL

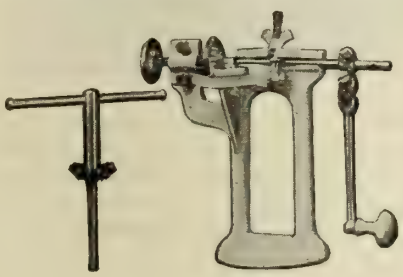
The mechanism that permits the slowing down of the speed of a boring mill spindle has recently been developed and placed on the market. By the addition of this mechanism a boring mill may be slowed down so as to perform the turning of tires on the same machine at a much slower speed. The attachment consists of a set of sliding gears, so that by sliding the small upper gear into the clutch of the large upper gear, a direct drive can be obtained so as to utilize the regular speed of the boring mill. A special cover is provided to protect all the gearing and also the shifting rod for sliding the gears into engagement. The arrangement makes a machine capable of both very high and very low speeds, and the device does not interfere with the operation in either range. These attachments are made by the Cincinnati Planer Co., Cincinnati, O., and have been designed for application to their own machines.

TRIANGLE BENCH SAW

An interesting type of portable bench saw has recently been developed and placed on the market. This saw is made in two sizes, the smaller one designed for cutting metal ⅛ to ½ inch dia. and the larger cutting from ½ inch to 1 inch dia. This saw is operated by ⅛ h. p., 110 volts, enclosed motor, arranged for either a. c. or d. c current. The shaft spindle is driven by means of worm gearing at a speed of 110 r. p. m. Provision is made for greater speed when cutting soft material such as brass and copper. Circular saws are hollow-ground and are 3½ inches in dia. x 1/32 inch thick. Work holding device is equipped with handle that permits of very rapid operation in clamping. The device clamps and holds square, round or hexagon stock without any change in the arrangement. An adjustable stop is provided for cutting the pieces off to the desired length. It is stated that rods of 3/16 inch diam. have been cut off with this machine at the rate of 18,000 ft. per hour. The machine weighs about 20 lbs. and is manufactured by the Triangle Metal Products Corporation, Rochester, N. Y.

VALVE REFACING LATHE

A small refacing machine for repairing valves of all kinds has just been placed on the market. This lathe is designed to be mounted on the bench or held in a vise and is adjustable to take any valve ¼ in. to ½ in. steam diameter and valve head up to 2¾ in. diameter, therefore its range of work is practically unlimited pertaining to its use in the automotive field. By lifting a gate in the top of the lathe, the valve may be laid in a V channel which acts as a guide for the valve stem while a tension screw holding the gate against the stem allows the valve stem to be rotated freely, yet it prevents chatter and vibration or a springing or distortion of the valve while in cut. The centering adjustment of feed control is mounted on a sliding block, traveling on a guide insuring accurate centers and even tension of the valve against



Valve Refacing Lathe.

the cutter, refacing the valve in perfect alignment with the stem, therefore a very meritorious feature of recognized importance is embodied in this tool.

Mounted on a very firm base is the cutter which is held in place by two screws, one acting as a pivot on which the cutter swings to the desired angle or degree while the other screw acts as a lock on the adjustment, holding the cutter firm and rigid. The crank which is attached to the end of the valve stem to revolve it against the cutter, is provided wih a tension slot and several adjustments to meet the varying valve stem sizes. Application of this crank will not mar the stem as no set screw or other cutting edge comes in contact with the stem. This lathe is substantially built, combines no complications or delicate parts and is universaly adjustable to all work within reasonable bounds. It is built by the R. S. Whitney Manufacturing Co. of Lewiston, Maine.

HIGH-SPEED TAPPING ATTACHMENT

A high-speed tapping attachment with a capacity of 3/16 inch taps in steel and ¼ inch in cast iron or brass has recently been placed on the market; the entire weight of the unit is only 3¾ lbs. The drive, both in the forward and reverse direction, is obtained through friction clutches. The drive is by means of two cones, the upper one directly connected to the shank which fits into the drill spindle. By means of a train of gears both cones are driven at the same time in the opposite direction. Between these two cones is a third conical member faced with leather on both sides. This centre cone is mounted on the spindle driving the tap by means of an Oldham coupling, so that it is free to centre itself on the two other cones, and does not tend to throw the spindle out of alignment when driving. The tapping spindle is carried and supported in a bearing in the lower half of the aluminum housings. Oil is delivered freely to the upper and lower bearing but provision is made for preventing the oil from reaching the leather friction surface. Phosphor bronze bearings are provided for the hardened and ground steel journals. The construction of the device permits the thrust to be transmitted to the main drill spindle. Owing to the purchase drive the speed of the tap can be regulated by means of the pressure applied to this spindle. A special type of tap holding chuck is provided which protects the tap against breakage, as it permits the tap to follow a drilled hole, in case the spindle is not in exact alignment. This device is manufactured by the Eastern Tube and Tool Co., Brooklyn, N. Y.

SCREW CUTTING DIES

An addition to the line of reliable two-part screw cutting die has recently been placed on the market. All commercial sizes are being manufactured. A special feature of the die is the manner in which the face is ground, so that the chips curl ahead of themselves instead of allowing them to fill and plug the clearance spaces. The principle applied is that of the comparatively well known "gun" tap to secure the same effect when cutting internal threads. It is claimed that the chips cannot become wedged in the clearance spaces and therefore cutters are less likely to be broken. These dies are manufactured by Conant & Donelson, Conway, Mass.

HIGH-POWER FILING MACHINES

A large-capacity high-power filing machine has recently been placed on the market. The length of the stroke is adjustable by means of an eccentric inside the column which is easily accessible. The eccentric is connected to the vertical sliding mechanism by means of a telescopic connecting rod, which permits the use of files from 3 to 14 inches long. A counter weight is provided for balancing the moving parts. The table has a surface of 24 x 30 inches and tilts for draft for clearance in four directions. The work clamping arm swings over the table and the pressure with which it holds the work down on the table can be regulated. By means of a cam inside the cone pulley the file on the upward stroke is given 1-32 inches relief. A constant flow of air on the file keeps this free from cutting. The lower arm can be adjusted so as to bring the edge of the file in line with the surface being filed. A four-step cone pulley provides speeds ranging from 80 to 320 strokes per minute. The length of the stroke varying from ½ to 7 inches. A half h.p. motor is provided, operating at 1,800 r.p.m. This machine requires a floor space of 22 x 38 inches and weighs approximately 700 lbs. The machine is manufactured by the Oliver Machinery Co. Grand Rapids, Mich.

Cost of Pig Iron Production

BUYERS of pig iron are sometimes at a loss in seeking an explanation of prevailing prices at 100 per cent. higher than those of eight years ago. The boast of $1.50 five weeks ago was not introduced without some protest reaching the producers, asking them to reconcile differences as between now and then. They were accused of an unwillingness to take losses on high-priced material "carried over." This charge was refuted as having absolutely nothing to do with present prices of pig. When one considers the high price of coal, as compared with that of 1914-15, he confronts an item that has contributed to upward trends in almost every line of industry. At that time coal was selling at $1 per ton at the pit, whereas it is doubtful if it has sold under $2 since 1920. Coke laid down from Detroit is about $12. Labor in the days of low prices was available at 16 and 17 cents an hour. It takes an average of four tons of material to make one ton of pig iron, in proportions of two tons of ore, one-half ton of limestone and one and a quarter tons of coke. Consider the fact that there is no tendency toward lower prices on any of these items, and that freight is on a much higher rate than in 1913, and you have the basis of the contention that the price of pig to-day is quite low. The producer who therefore, in reply to a protest, stated that the business was not attractive at the present time, evidently had in view the fact that fundamental costs are still maintained by conditions over which he had little or no control. Further reductions in freight rates, and the settlement of coal strikes should be a factor in relieving the situation.

Problems Of Isolation

"OUR FUTURE depends on the revival of our foreign trade. Forty millions of people in a small island cannot live on taking in each other's washing," was the recent comment of Lord Riddell in a discussion of Britain's overseas trade. He thus touched upon problems of isolation which, about the same time, formed the theme of a speech by Thomas B. McAdams, president of the American Banker's Association, at their annual convention. He emphasized a fact which sometimes seems to be purposely lost sight of by public men in the United States, that such portions of Canada's production of three hundred millions of bushels of wheat as may not be needed for home consumption will come into direct competition with the United States in supplying the food demand of the world. "Shall we encourage isolation," said Mr. McAdams, "which can only result in loss to both countries, or shall we map out a broad-minded partnership under which Canada and America can work hand in hand in the development of the other's resources, and the broadening of their mutual business relations and unitedly co-operate in bringing to North America the trade of the world?"

Of course, it is presumed the term partnership here is used in its broadest meaning and carries with it no suggestion of national absorption. The expression is interesting as being representative of a purely business rather than a political viewpoint.

Problems of the Situation

REVIEWING economic conditions as they affect the machine tool industry in the United States, the National Machine Tool Builders' Association considers the matter under seven headings—demand, capital, labor, material, fuel, transportation and equipment. The claim is made that pig iron production being up to 70 per cent. of previous maximum, the machine tool demand should come along. Further, the contention is that radio and auto industries have given plans to many machinists until the tool builder faces labor shortage and increased cost due to high wages and low efficiency at the time machine tool demand will actually appear. Material prices are advancing and likely to go higher, car shortage will be apparent if business continues to increase at the same rate of increase as in the last three months, and the low demand for machine tools shows plenty of equipment.

The review is interesting since it refers to conditions as affecting a large market and discusses such influences as restriction of immigration and its bearing upon the labor market, the likelihood of a coal shortage and the extent to which substitutes such as oil and coke are being used and the fact that railroad equipment is not adequate to meet the demands of a strong comeback.

Canadian conditions considered under several headings would reveal, of course, that here the market is not self-contained or self-sufficient, so far, at least, as materials are concerned, and hence is more or less influenced by outsde developments. The demand for machine tools while still below normal, is showing more life, with an improvement in the woodworking section. The banks say they are meeting the requirements of industry, but that in the past six months there has not been much demand except as regards specialties as in contrast with standard lines. The labor market shows a healthy condition as far as laborers are concerned, with the skilled section still subject to seasonal or spasmodic tendencies. So far as materials and fuels are concerned, the market in the former is decidedly firm as reflecting conditions in the United States, with a strong demand from building operations, motor car industries and requirements for public works. The fuel situation as yet has not developed the aspects of a real problem and, it is hoped, may be solved shortly. There are few labor problems in sight, and as one manufacturer put it, "we seem to have a fair foundation for better business."

Coal and Rail Strike Serious to Steel Industry

Production Figures Revised But Still Show Increase of Thirty-Five per cent.—Canadian Business Continues Good—Steel Bars Advance 10 Cents—Turpentine Recedes to $1.65—Strong Demand for Sheets of All Kinds—Shortage of Specials

IMPLEMENT INDUSTRY BUYING PIG IRON

THERE IS a more serious tone to the iron and steel markets this week on account of strike developments in the coal and railroad industries. Production may have to be curtailed, to what extent is problematical, and reports from Pittsburg indicate that, as a result, the sellers' market may be prolonged. Estimates as to steel ingot production are being revised, but the increase for the half year is on a basis of 35 per cent. The actual production in the second quarter of the year was about equal to that for the entire second half of last year. The output in the past few weeks, however, is about 10 per cent. less than previously estimated, and does not represent a material increase. There is less prospect, therefore, of consumers being overstocked.

The Canadian market, in spite of seasonal tendencies, appears to be holding up well. There has been an advance of 10 cents in iron and steel bars, the maximum figure now being $3.25. There has been a persistent movement in this direction for some weeks. An advance of one cent in copper products is also announced this week. The reason given for this is that war stocks of materials have been pretty well absorbed and there is a greatly improved demand. There is a great market for sheets of all kinds. The prices are firm, the supply in specials is decidedly short. This is a reflection of the activity in building and in the motor car industry.

There has been a recession in the price of turpentine. Due to short supply and strong demand, prices showed an inclination to run well over $2.00 the gallon. For the present week, however, the price in barrel lots is given as $1.65, or $1.75 per gallon. The market for the time is in better shape, but dealers say they have here an item that has a tendency to fluctuate daily.

So far as pig iron is concerned, the agricultural implement industry is in the field for fair sized tonnage, not only covering in a reasonable way for future, but responding to an improved demand. Some very nice orders have recently been received from France for this industry, and of course, Western prospects contain sufficient cause for an amount of optimism.

The demand for machine tools continues light, but dealers declare there are times when the market develops quite a little spurt. In some quarters there are reports that the past week showed an improvement. There is a certain volume of inquiry, and the feeling is that this, of itself, indicates a healthy underlying condition. Just when it will break out is the question. Machine shop supplies continue in fair demand.

The Montreal market, though running into that part of the summer that is proverbially quiet, still reports activity in many lines. There is a marked demand for galvanized sheets and the supply is not what it should be. There is a firmness in non-ferrous metal and here slight advances are recorded. Large foundries, having covered their requirements in pig iron, that market has eased off a trifle. In shop supplies there is a demand developing in which the railways are conspicuous, although they have not appeared in such a way as to predict any general improvement of the market from that source. In fact, while there is a general undertone of confidence in the Montreal market, no radical changes are looked for until September.

Toronto

July 19

OUTSTANDING features of the Toronto market this week, include an advance of 15 cents in steel and iron bars, the maximum quotation on this item being $3.25 per cwt. and the minimum $3.15. An advance on copper and brass products of one cent a pound is also announced following a slight advance on the American market and the fact that large stocks of so-called war material have been absorbed. Turpentine may also be included among the week's active items, but this time it has made a considerable recession, and not an advance as was the rule in the past few weeks. Some quotations were in the vicinity of $2.00, but the price, barrel basis, is given as $1.65 or $1.75, gallon lots. The market appears to have a better supply in sight. The pig iron situation reveals the fact that the agricultural implement people have been buying in fair quantities. There does not seem to be much prospect of an easing in price at present. The reduction in freight rates will hardly manifest itself as a reducing factor this year, as materials to cover immediate requirements are pretty well in hand. Furnace men state that there is not much likelihood of better figures here until conditions have some stability and are more normal. In fact, there are those producers who declare that pig iron business at the present time is not what might be called attractive. The fact that buyers are inclined to base protests on a comparison of prices as between 1922 and 1914, brings forth the explanation that coke, limestone, ore, labor and freight, in short all factors entering into pig iron production, are still at high levels with no likelihood of marked improvement.

Scrap metal dealers declare that there is little activity in their department. There is a tendency toward firmness in copper, but this is hardly sufficient to cause a ripple on a placid surface. Not a great deal is being offered, and the buying while fairly steady does not run into large quantities. The price range follows:

Copper, light ... ... per 100 lbs.	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper Wire	11 00
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings ...	4 85
Light brass	3 50
Medium brass ...	4 50
Scrap zinc	4 00
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton ...	9 00
Heavy melting steel ...	11 00
Axles (wrought iron) ...	16 00
Rails (scrap)	11 00
Malleable	11 00
No. 1 machine cast iron ...	16 00
Pipe, wrought ...	6 00
Car wheel	16 00
Steel axles	15 00

The advance of 10 cents in iron and steel bars seems to be the outstanding feature of the week. There has been a movement in this direction for some time and while it did not appear to be general, the mills finally confirm conditions on which the strength developed. The demand is exceptional. Prices follow:

Iron bars	3 15 to 3 25
Steel bars	3 15 to 3 25
Reinforcing bars	3 15 to 3 25
Steel hoops	4 00
Tire steel	3 15
Spring steel	7 00
Band steel, No. 10 gauge and 3-16 in base	3 65
Small shapes	3 25
Sheets, black, No. 28	5 00
Sheets, blue ann., No. 10 ...	4 00
Canada plates, dull, 52 sheets	4 90
Canada plates, all bright	6 00
Galvanized Sheets, No. 28	6 00

In the non-ferrous department, the market is showing a tendency that seems to be in unison with the general market, that is toward definite firmness. New York markets reveal this, but so far as the Toronto market is concerned no definite change is reported.

Lake copper	17 00
Electrolytic copper	16 50
Castings, copper	16 00
Tin	34 00
Spelter	7 25
Lead	7 00
Antimony	7 40
Aluminum	21 00

Machine tool demand continues quiet. Last week there was an improvement in some quarters. There is an encouraging demand for machine shop supplies.

The upward tendency in cotton ma-

terials continues. A three-cent advan- in cotton twines is reported, three-plies are 39 and four-plies, 42 cents.

The demand for steel sheets continues exceptionally strong, indicating not only the activity in the motor car industry but also that of building operations. Certain specials are difficult to get. Deliveries, it is reported, are not as good as demand should have.

Montreal

July 19

THE DULLNESS that is usually looked for in the iron and steel industries at this season of the year, has held off longer than was anticipated. July business up to date, is about equal to that of June for the corresponding period, but as the first ten days of this month showed excellent business, it will be seen that there is a slight reduction in the volume of business as compared with the first of the month. For the last week business has been spotty, one jobber will be moving certain lines while others will be getting business from entirely different sources in other products. The one steel item, that seems to be in common demand, is galvanized sheets. As has been reported from here for some weeks past, the supply does not equal the demand. Other lines of steel and iron are moving satisfactorily but not to the same extent. Pig iron sales are falling off a little. Machine tools remain the same as last week, continuing to be rather dull. Shop supplies are moving quiet as well as last week. There is a firmness in the non-ferrous metals, especially in copper, brass and spelter. The scrap metal markets are quiet. The general consensus of opinion among dealers and jobbers, is that there will be but little changes between now and the first of September. The year's business has been unusual in many ways but there appears to be the opinion that we cannot hope to escape the quiet summer period. There is exhibited, however, a great deal of confidence in the general situation, as reports from the United States are that, in all lines, business is improving, and from Western Canada the prospects of crop that is better than average, will all tend to help matters to a considerable extent. The rail haul will be of such importance that the railways will come into the market and help business in some of the larger shops that depend on the roads for the larger portion of their work. The requirements of the West in the line of manufactured goods will be increased as soon as the crops are harvested. Some prominent men are inclined to compare the present situation with that of last year, and in so doing, they appear to have good reason to express satisfaction.

Iron and Steel.—Although in some quarters there appears to be curtailment in buying, no serious falling off in the volume of business moving has been reported. Galvanized sheets are still featuring the market. It is stated there were nearly one thousand tons of galvanized sheets on the ill-fated steamer "Ortha" that was beached after a collision about a week ago. The Montreal consignees of this material have arranged for the goods to be replaced and hope to have same in Montreal early in August. This is much better delivery than it was possible to obtain for some time back. Production in the British mills is being increased, as there is no falling off in demand. Structural steel continues to be absorbed in medium and small lots, and up to time of writing no general attempt has been made to replenish the stores that are being more or less rapidly depleted. The call for merchant bars is being maintained at about the same level. The improvement in the demand is slow but steady. Small steel products are still being disposed of in very satisfactory quantities. The only steel product that is really dull, is plates. Miscellaneous products such as reinforcing bars, tire steel, hoops, band steel, etc., are moving well. There have been no changes in quotations during the week, but as there is a range of ten cents in the base quotations a little margin is given here. Large orders command somewhat closer prices than the smaller ones. On the whole there is a general stiffness to all quotations and but little price cutting is reported. The following are the local quotations:

Iron bars	3 15 to 3 25
Steel bars	3 15 to 3 25
Reinforcing bars	3 15 to 3 25
Steel hoops	4 00
Tire steel	3 15 to 3 25
Spring steel	6 00
Band steel, No. 10 gauge and 3-16" base	3 25
Small shapes	3 00

Pig Iron.—The splendid demand for pig iron that was present two weeks ago has practically spent itself. At the attractive quotations given at that time with a firmer market promised, many foundries covered their requirements for some time to come. The natural result is that purchasing has dropped off considerably. The smaller foundries are still coming into the market frequently for one or two cars, which factor is responsible for practically all the sales made during the week. The Summerlee iron is still available on the local market and is being disposed of in small quantities. It is more than probable that this iron will be on the Canadian market until the close of navigation. If the demand increases in the autumn, a good tonnage will be imported to take care of winter requirements. No changes in price have been made during the week, Summerlee still being quoted at $29.75 on dock and No. 1 Canadian product at $31.85.

Machine Tools.—Iron working tools are still moving very slowly. Very few sales have been made. There is evidence that more or less interest is being maintained in this line, because there are a fair number of inquiries. The large amount of idle equipment locally, is responsible for the small volume of sales. Some firms manufacturing radio equipment have purchased a few odd small machines lately. Outside of this work there is only a small amount of manufacturing in the local shops. Portable tools are moving rather well. Some of the large garages operate a small machine shop, and are good prospects for many electric and air driven portable tools.

The lumber industry and the furniture manufacturing firms are rather active and this activity has resulted in a little business in wood working tools.

The railroads have not come into the market for new equipment and thus far dealers have been unable to interest them. Prices have reached a level at which they will likely be maintained for some time to come.

Shop Supplies.—The shop supply business continues to improve form month to month, even if improvements connot be noted when comparing weekly figures. The large number of repair shops and contract shops in the province, all appear to have a very satisfactory quota of work and these firms come into the market regularly. The railways, together with the larger shops are furnishing a fair amount of business. Prices have not undergone any important revisions during the week, and sales about equal in volume to those of last week, were made.

Non-ferrous Metals.—A rather strong undertone is felt in the non-ferrous metals. Copper, brass, and spelter are very firm, quotations were advanced a quarter of a cent a pound on the local market. Both New York and London markets are reported as being firm. Sales have improved slightly during the week. The demand has been very scattered and few large lots have been sold. Other metals are firm and are moving as well as at any time in several weeks. The local quotations are as follows:

Lake Copper	17 75
Electrolytic Copper	17 50
Castings, Copper	17 25
Tin	34 50
Lead	6 75
Spelter	7 75
Antimony	6 50
Aluminum	**23 00**

Scrap Metal Markets.—Very little activity has been evidenced in the local scrap metal market. Sales locally have been small. Some sales have been made to outside points. These shipments have gone to Ontario largely, but a few have been made across the border. Holdings locally are small. There has been no change in quotations which are as follows:

Copper, light, per 100 lbs.	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper Wire	11 00
No. 1 compositon	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 00
Light brass	4 00
Medium brass	5 50
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	20 00
Pipe, wrought	7 00

Pittsburg

July 19

CONTINUANCE of the recent rate of pig iron and steel production is very seriously menaced by the railroad strikes and coal strike developments. There is a strong balance of probability that there will be a little decrease in the next few weeks, and it is possible there will be a very considerable decrease. It is unlikely that consumers will be seriously incommoded, but the condition of there being a sellers' market in steel will be prolonged. How long the sellers' market will last no one can predict definitely, but it will last longer than it otherwise would have lasted.

As to the railroad developments, before the end of June some little congestion has developed on railroads serving non-union coal fields, particularly in Kentucky and West Virginia. The non-union fields, outside of those that had sympathetic strikes in connection with the regular union strike (of the United Mine Workers) that began April 1, had been shipping unusual quantities of coal and to unusual distances. On top of this natural congestion, which might have developed to serious proportions, came the strike of railroad shopmen, July 1, crippling all roads at least a trifle, and greatly crippling the roads already congested. Now there is danger of some other groups of railroad workers also going on strike. Thus by reason of transportation conditions supplies of coal have been very considerably reduced, and several by-product coking plants are feeling the effect.

Then, as to the coal strike, President Harding initiated a movement late in June to end it. Thus far the practical outcome of the Washington effort has been that the coal strike is much worse, in three respects at least; (1) In some non-union regions, where there had been sympathetic striking, this striking has increased. In the Connellsville region in particular, where it was altogether phenomenal for non-union men to stay out three months on a strike, when they have not had practice in striking like the union miners have had for a generation past. The strikes had been waning, quite gradually it is true, but still waning, and expectations were that by this time men would be coming back in numbers. Instead, immediately after President Harding's proposal fresh striking broke out in the Connellsville region. (2) Some union operators had made plans to attempt to start mines July 5, and whether the operators postponed the effort or the men acquired fresh courage and refused to return to work as it is alleged they had promised to do if given protection, no union mine in the Pittsburgh district has resumed. (3) The President's taking a hand in the particular district in which he did has given the United Mine Workers officials an idea that they can secure the unionization of some of the mines long non-union. Thus while last March the average bystander could hardly avoid the conclusion that the United Mine Workers would come out of this struggle decidedly weakened, the officials apparently think now they are going to come out of it stronger than ever. Instead of losing some mines hitherto union they evidently have hopes of getting some mines hitherto non-union.

President Harding's proposition cannot be discussed in detail, but the salient features are that the mines should resume work at the 1920 scale, an extremely high one, pending a finding of a commission to be established, while it is doubtful whether the commission could reach a conclusion in anything like a reasonable period and the men might start a fresh strike against the award, and the language of the proposal seems to intimate that instead of the mines resuming their former status, an indefinite number of mines formerly non-union are to be unionized. In trade circles the prevalent opinion is that the President was very poorly advised before making his proposal.

Steel Production.—Estimates recently made as to the rate of steel production must be revised materially. The publication not long ago of complete statistics of production in 1921 gives a fresh line on the proportion of the total output furnished by the 30 companies which make monthly returns of their ingot production, while the June report shows that there was an increase of less than one per cent. in the rate from May to June, whereas it was generally believed that there was a material increase. Increases were reported at various individual plants in June, and these increases no doubt did occur, but evidently there were decreases at other plants about which little or nothing was reported.

Revised estimates are that the annual rate of steel ingot production was 35,500,000 tons during April, 36,400,000 tons during May and 36,600,000 tons during June. The average rate during the first quarter of the year was about 26,800,000 tons a year, the average during the second quarter being about 36,150,000 tons, making an increase of 35 per cent. By another comparison, the actual production in the second quarter of this year was just about equal to the production in the entire second half of last year.

Thus there has been a great increase in production, at long range, but the production in the past few weeks has not represented any material increase and is about 10 per cent. less than recently estimated.

The balance between production and consumption is not altered by the revision in estimates, as there had been no estimate of consumption other than that derived from shipments, but it looks easier for consumption to absorb the production than it did, and there is less prospect of consumers being overstocked. Scared by the coal strike, consumers might easily have piled up too much steel, then starting to liquidate if they saw the coal strike ended and prospects of there being unlimited suppliees of steel. As matters stand, there is little prospect that it will be possible at any time this year to make steel at a much greater rate than of late. There would have to be much more disposition to mine coal, much bteter transportation conditions, and larger supplies of labor at steel mills. At several points lately scarcity of labor has developed at steel mills.

The steel market has been relatively quiet in the past week, as to the total turnover. Most lines are seasonably dull. The mill position continues very strong. Bars, shapes and plates command slightly greater premiums than formerly for early deliveries. Basic prices, for late deliveries, are practically unchanged on all commodities.

Pig iron has weakened somewhat in some districts, Alabama iron being down 50 cents to $18 Birmingham, while basic pig iron in the valleys has been done at $24, furnace, against $25, firm, quoted as the market during May and June. It is curious that there should be anything like a weakening in pig iron when coke prospects have just become decidedly poorer. It seems that buying demand has been lighter right along than was expected. A number of consumers are spreading over third quarter deliveries they had originally bought for second quarter entirely.

INDIA A LARGE PURCHASER

No other industry in India makes such large purchases of materials as the railroad industry. During the fiscal year 1920-21 the railways spent nearly $100,000,000 in purchases of materials, more thon half of which were imported from the United Kingdom. The chief materials purchased in India are rails, bridge work and wooden sleepers, while a start is being made at turning out parts of wagons and coaches. The extent to which the steel industry has progressed in India is shown by the purchase of rails in the country. In 1920-21 rails to the value of 62 lakhs of rupees were purchased in India as compared with 14 lakhs in 1915-16. This progress is almost entirely due to the enterprise of Messrs Tata and Sons, steel manufacturers, established in India in 1921. The United Kingdom, supplied about 97 per cent of the huge total of about $60,000,000 worth of supplies, Canada coming next, supplying several hundred thousand dollars' worth of special hopper wagons for coal and ore.

The Diamond State Fibre Co., 235 Carlaw Ave., Toronto, have secured some good orders from the Ford Motor Co. of Canada. Mr. Webster, manager of the Toronto factory tells Canadian Machinery that their fibre is used in various parts of the Ford motor, such parts as commutator rings, insulation parts, etc., being quite extensively used.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

PIG IRON

Toronto price:—

News From the Industrial Field

Henry Ford is reported to be seeking a site in Mexico for an automobile building and assembly plant.

The Booth Coulter, Copper and Brass Co., Toronto, have added to their products, a line of art brass goods.

Dennis Wire and Iron Works Co., Toronto, has secured the contract for the ornamental iron work in connection with the technical school at Riverdale.

The steel contract for the two additional stories to the Telegram building, Toronto, has been awarded to the Dominion Bridge Co., of Toronto.

While oiling a machine in the plant of the Rodney Woodenware Co., Rodney, Ont., George Robinson, 60, was caught in the wheels and killed.

The Heine Boiler Co. St. Louis, Mo., are desirous of arranging with a Canadian firm to manufacture their boilers here for Canadian Export trade.

The steel work for the new machine shop to be erected by the Ideal Iron Works at Vancouver, B. C., will be supplied by Jas. Layfield Contracting Co. of Vancouver.

The A. R. Williams Machinery Co., Toronto are installing in Sarnia Technical School a Hisey-Wolf grinder, a Dumore tool post drill, and transmission equipment.

Unemployment relief during last winter cost the Dominion Government $1,300,000. One half of this was direct, while the other half was contributed through local authorities.

In our issue of July 13 appeared an article on Getting Service and Output from Sawing Machines. Credit should also have been given to Clemson Bros., for information supplied.

While American railroads are buying large quantities of material for renewal of rolling stock, Canadian roads state that their equipment is in good shape, and that practically no purchases are being made in that connection.

William H. Biggar, K. C., vice-president and general manager, G. T. R., died in Montreal July 7, after a brief illness. He was born near Belleville, 69 years ago. Called to the bar in 1880, he became solicitor for the Grand Trunk in 1910.

Kingston.—Building contractors in Kingston are on the outlook for work on the block surrounded by Wellington, Clarence, Bagot and Johnston Streets, the centre of which was totally destroyed by fire on the morning of July fifth. Eleven buildings were damaged and three of them totally destroyed.

The Durant Motors of Canada are now prepared to receive tenders for the erection of the new addition to their plant at Leaside. Plans are open at the office of E. A. Walberg, Room 909 Royal Bk. Bldg., Toronto.

The Tegles Construction Co., of Fort William has been awarded the general contract for the construction of the $500,000 grain elevator to be erected by M. M. Patterson Co., of Winnipeg, at Fort William, Ont.

G. H. Regan, district manager at Montreal for the Diamond State Fibre Co., Carlaw Ave., Toronto, is leaving on his vacation for two weeks. In the meantime enquiries will be taken care of at the Montreal office in the usual way.

In an effort to further the development of trade between Canada and foreign countries, Dr. J. W. Ross and Major G. B. Johnson, Canadian trade commissioners respectively for Shanghai China, and Glasgow, Scotland, will visit Canada shortly to get in personal touch with various exporters.

The Dominion Bridge Co., Toronto, have issued for circulation in booklet form, their current stock list of steel shapes and other metal products for immediate shipment. The booklet contains items as to weights, safe loads for beams, channels, angles, etc., and general information.

Kingston will next year celebrate its 250th birthday. The city was founded by Frontenac in 1672. Chief among the things to which the Kingstonian points with pride is the Canadian Locomotive Works, not as active to-day as they should be, but there are signs of better days approaching.

That a large industry would shortly establish a plant at Sault Ste. Marie, Ont., was indicated by a statement made by W. C. Franz, president of the Algoma Steel Corporation at a recent dinner of the Board of Trade.

Details as to the industry were not announced, but it is understood that it gives promise of being a very large affair, with a Dominion-wide business.

According to statistics from the Department of Labor, Ottawa, there was a slight decline for June in the index of wholesale prices, while the index of retail prices for food, fuel and rent show a very small increase. The total for food, fuel and rent averaged 20.58 for June as compared with 20.50 for May and 21.74 for June 1921. This decline in the food budget was due almost entirely to the decreases in sugar and in dairy products, except eggs which advanced slightly.

John Gray, Collingwood, formerly in the employ of the Shipbuilding Co. there, has organized the **Georgian Bay** Spring and Metal Co. to specialize in springs used in motor car and other industries.

The executive offices of the Canadian National Railways may be removed from Toronto. It is hinted that the Government may end the controversy as between Toronto and Montreal by establishing a nominal headquarters, where the Board of Directors will meet, at Ottawa.

Vancouver, British Columbia.—During 1921 the total gross tonnage of shipping (sea-vessels) out of this port was 2,659,366, representing 389 vessels, an increase of 53 vessels over 1920. In addition 107 foreign coastwise ships left the port, increasing the tonnage to 2,946,659.

Sir Robert Horne, chancellor of the Exchequer, declares that Great Britain is stronger financially than at any time since the armistice. At present rates of exchange her debt to the United States was £938,000,000. The recent reduction of her floating debt and also of the internal debt had increased financial stability throughout the country. He regarded the debt to the United States as a solemn obligation.

Sydney, N. S.—The billet and blooming mills at the Sydney steel plant are now working double shift, according to a statement issued by the British Empire Steel headquarters. This new activity will increase the force to over 2,300 men. For the first time in the twenty-two years of its history the plant has successfully entered the foreign market for finished steel products. Orders are on hand for nails, barbed wire and galvanized wire for Buenos Aires, South Africa, New Zealand, Costa Rico, Colombia, India and British West Indies.

Axel Lindstrom, Cape Town, South Africa, who recently arrived in New York to look over the machinery field, states that capital is needed in that colony to help develop vast resources. He states:—"We complain there about our taxes, just as people do the world over, but our taxes are only 1 shilling 6 pence, as against 6 shillings in England, showing that we are not so bad off after all. Most things are cheaper there than in this country, and one can live in the best hotel in Cape Town for $5 a day including meals as well as a room. A good suit of clothes, such as would cost $60 or $75 here, can be bought there for $40. For good workers in unskilled labor one pays less than $1 per day in Cape Town."

Cox and Wilcox, contractors, have been awarded the contract for the erection of a four roomed addition to Franklin school, Fort William, at a price of $53,447.06. Work will commence immediately.

The Hamilton Bridge Co., has secured the steel contract for the new factory of Dominion Dress Goods Co., at Brantford. The steel sash work goes to the Trussed Concrete Steel Co., of Walkerville.

Hamilton, Ont.—The Canadian By-Products Co., has been incorporated here under a Dominion charter with a capital of $600,000 to manufacture firebrick and refractories from anthracite ash. A plant is to be erected immediately and it is expected actual manufacture will be under way before the end of the year.

Toronto.—The Ontario Government has decided to encourage the development of the extensive iron ore deposits in the northern districts of the province, and has called a conference of experts and others interested in this industry. One of the matters to be considered is the use of hydro-electric power for smelting, there being an abundance of such energy in Northern Ontario.

London, Ont.—The London Bridge Works, Ltd., recently incorporated with a capital of $100,000, are starting operations here immediately. It will have a fair-sized plant, with a monthly capacity of about 250 tons of fabricated steel for bridges and buildings. In addition to the fabricated steel business, the company intends to build and equip a large warehouse for the distribution of steel products of all kinds, including structural steel shapes, steel plates,

Speaking to Mr. Downer, of the Downer Pattern Works, 265 King St., W., Toronto, Canadian Machinery found that business is picking up for this firm very nicely. They have just completed a monstrous wooden model of an Underwood typewriter, this being for exhibition purposes. It will be shown from coast to coast, and you could place 3,375 regular size machines in the space occupied by this huge model. Canadian Machinery had an opportunity of looking over the work which is so out of the ordinary that it cannot help but command attention.

Montreal.—Records of the grain shipments from the port of Montreal for the season of 1922 go to show that up to the first of July the record of 1921 has been exceeded by almost half a million bushels. There is every indication that this record will be maintained. The elevators have at present all the needed varieties in store for the many grain ships due from the Atlantic. The stocks contain Canadian and American wheat, Canadian and American oats, barley, American corn and Canadian and American rye. Forty million bushels of grain have already been shipped through the port of Montreal this season.

Introducing

JAMES D. JONES

Superintendent Algoma Steel Corporation Sault Ste. Marie, Ont.

To be general superintendent of a plant such as that of the Algoma Steel Corporation, Sault Ste. Marie, with its blast furnaces, its blooming mills, its rail and structural steel departments and multitudinous other activities, would seem to be a fair sized order for any man, no matter how efficient. But James D. Jones, who fills that position, can find time occasionally to function elsewhere. He impresses one as being young in years, but when he discusses different phases of the steel industry, it is evident he has not lost any time or overlooked much as regards what has been done and what might still be accomplished.

Readers of Canadian Machinery renew their acquaintance with Mr. Jones whenever the ore resources of Ontario are being considered. At the recent meeting before Hon. Harry Mills, minister of mines, to investigate the feasibility of a native blast furnace industry, Mr. Jones told the metallurgists and mining men present some significant things. He knows from experience just what can be done with the siderite and magnetite ores that predominate in Ontario. The famous Magpie mine was operated for some time by the Algoma Steel Corporation, and it was found that by mixing its siderite ore with magnetite in certain proportions, an ore was procurable at $1.57 cheaper than anything of the same grade from straight American ores. Mr. Jones is an authority on beneficiation and after visiting many important plants in the United States, declares that there are apparently no problems in Canada that are not existing and are being successfully solved in the United States. With proper study of ore conditions, in order to produce desirable grades, and with the development of organization, it is his opinion that a market will be available for all of the Canadian ore that can be produced.

One thousand men are now on the payroll of the Port Arthur Shipbuilding Co., the largest number attained for six years. Work is being rushed on the new lake freighter Matthewson, and over seven hundred workmen are engaged upon her hull and fittings.

Announcement mas made July 14 that the Consolidated Water Power and Paper Co., of Wisconsin Rapids, purchasers of the plant of the Kaministiquia Paper Co. at Current River, Port Arthur, were contemplating large extensions to the plant. Just how big the plans of the company are will not be known for some days.

The International Business Machines Co., are now displaying a complete line of Dayton Scales, International Time Recorders, etc. At their new sales and service store, 32 King St. West, Toronto. The new office and show room is centrally located in Toronto's downtown section. Demonstrators are in constant attendance to explain the operation of any of the company's products, and interesting window displays are regular features.

The huge increase in India's machinery importations during the past year, is explained by the fact that the Indian jute mills, textile establishments and other industries spent a large proportion of their unusual profits of the preceding years in replacements of and additions to plant, which had been held up during the war. That machinery imports are still maintaining this advance is evidenced by the returns for the month of March, 1922, machinery to the value of no less than 3.27 crores, or about 10 million dollars, being imported during that month, as compared with a value of 2-94 crores during the month of March, 1921. Of the year's total of 34 crores the share of the United Kingdom was 28 crores, of the United States 4½ crores, and of Germany one-half crore.

Some explanation of the improvement in industry in United States is found in the fact that the railways are in the market for very extensive renewals of rolling stock. Canadian roads are in pretty fair condition in this particular line but are now buying good tonnages of track material. As an example of what is taking place among American roads, the Illinois Central is receiving bids for from 500 to 1,000 gondola cars. The Western Pacific has placed an order for 2,000 refrigerator cars with the American Car and Foundry Co. The Northern Pacific has ordered 250 gondola cars from the Standard Steel Car Co. The Norfolk and Western has divided an order for 2,000 hopper cars as follows:—American Car and Foundry Co., 500; Standard Steel Car Co., 500 and Pressed Steel Car Co., 1,000. The Illinois Central has placed an order for 20,000 tons of rails with the United States Steel Corporation and the Ann Arbor road has ordered 1,800 tons of rails from the Midvale Steel and Ordinance Co.

Last week a building permit was issued for the erecting of a million capacity storage annex to the N. M. Paterson grain elevator in west Fort William. Construction of the addition was commenced some days ago and work is progressing rapidly. The Fegles Construction Co. are the builders. The new plant will be of reinforced concrete construction.

Building operations in connection with the erection of a paper mill at the present site of the Fort William Paper Co., are proceeding rapidly and the last of the many hundreds of concrete piles are being sunk. The new paper mill will consume the ground wood pulp of the pulp mill which has an output of approximately 110 tons of dry pulp daily.

Niagara Falls, Ont.—The Canadian Shredded Wheat Co., is enlarging its plant here, by the erection of wheat storage bins and cleaning room. These are being built of concrete and when completed will give storage capacity for 250,000 bushels and a cleaning capacity for 250 bushels an hour. The building will all be fireproof and will be completed about October 1st, at an estimated cost of $152,000 for buildings and equipment.

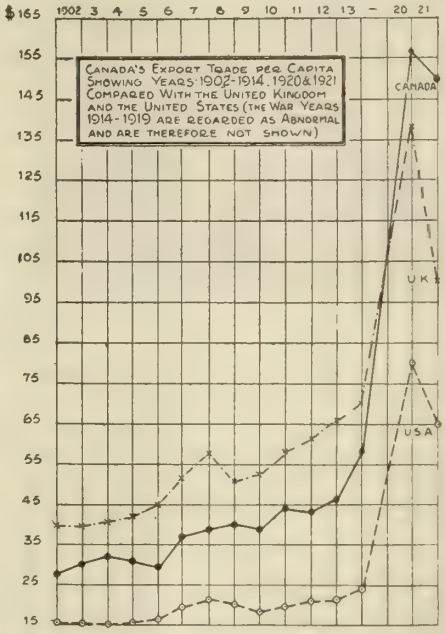
According to trade commissioners' reports, the British motor industry has lost considerable business because of the eleven-week engineering lockout, recently settled. Manufacturers state that many prospective purchasers have withheld their orders for the year and that other large orders have gone to other countries. Certain makers are well stocked with chassis. The Rolls-Royce and several other large plants were forced to shut down in early May. A few nonfederated firms turned out more cars during the lockout than ever before in their history. Small cars and several makes of motor cycles are much in demand, and firms manufacturing them have orders for several months' production. Prospects for the sale of new heavy trucks are poor, due to the stocks of about 12,000 army supply trucks obtainable at prices representing only a fraction of their original cost.

IS CANADIAN LOCOMOTIVE CHANGING HANDS?

Within the past two or three weeks there has been much talk and speculation around Kingston, in regard to the large plant of the Canadian Locomotive Co. There was a rumour to the effect that a large American concern had secured an option on the plant and the Baldwin Locomotive Co. was mentioned. Nothing definite has been announced as yet, but an official of the company admitted the giving of an option to some concern. The strength of Canadian Locomotive stock on the market tends to confirm the rumour of a purchase and operations in the near future. Although there has not been much trading, the common stock has been going around 78 on the Montreal market, a good showing for a company which has not been producing for many months. The people of Kingston are awaiting a definite announcement as the big plant is the most important industry in the city.

CANADA'S EXPORT BUSINESS

Ottawa, Ontario.—Canada leads the world in volume of exports per head of population. Computations made by the Department of Trade and Commerce show that Canada's exports now amount



Canada's export trade per capita.

in value to $150 per capita, as compared with $98 for the United Kingdom. In 1902 Canada was exporting products to the value of $28 per capita, as compared with $40 per capita in the United Kingdom and $15 per capita for the United States.

IMPLEMENT MEN EXPECT AVERAGE CROP

REPORTS received by the agricultural implement industry would seem to indicate that while crop prospects have been shaping favorably there are some doubtful factors which seem to detract somewhat from expectations for a bumper yield. One authority, for example, states that conditions have not been good in the territory west of Saskatoon and that Southern Alberta, owing to continued rains, is not coming along favorably. "I am rather inclined to the conservative view that we are not going to have a bumper crop but that rather, it will be a pretty fair average," said the manager of a large concern having extensive dealings with the agricultural community. "Of course, one may be somewhat premature in making predictions. Given a favorable summer, such conditions that now seem discouraging may be overcome, but speculation at any time should be exceedingly cautious."

Reports coming from Western sources state that the outlook at present is certainly better than it was at the same time last year. There has been some damage from frost, drought, insects and hail, but the total damage does not appear large or serious.

So far as export business in agricultural implements is concerned, France is the only European country that is doing any considerable amount of buying, and here it is on a scale that is fully up to the average. Germany is doing very little buying at the present time, but it is the opinion of the authority quoted above that economic processes going on there will eventually bring that country to world levels in the matter of selling, and that she will appear as a more or less aggressive buyer of certain lines once her abnormal problems are in hand. The same may be said of Russia, but here nothing definite can be said of the perspective.

OBITUARY

W. E. Dyer, assistant superintendent of the Ontario Malleable Iron Co., of Oshawa, and a resident of that town for over half a century, died last week from complications following an attack of influenza.

OTTAWA AND DICTRICT

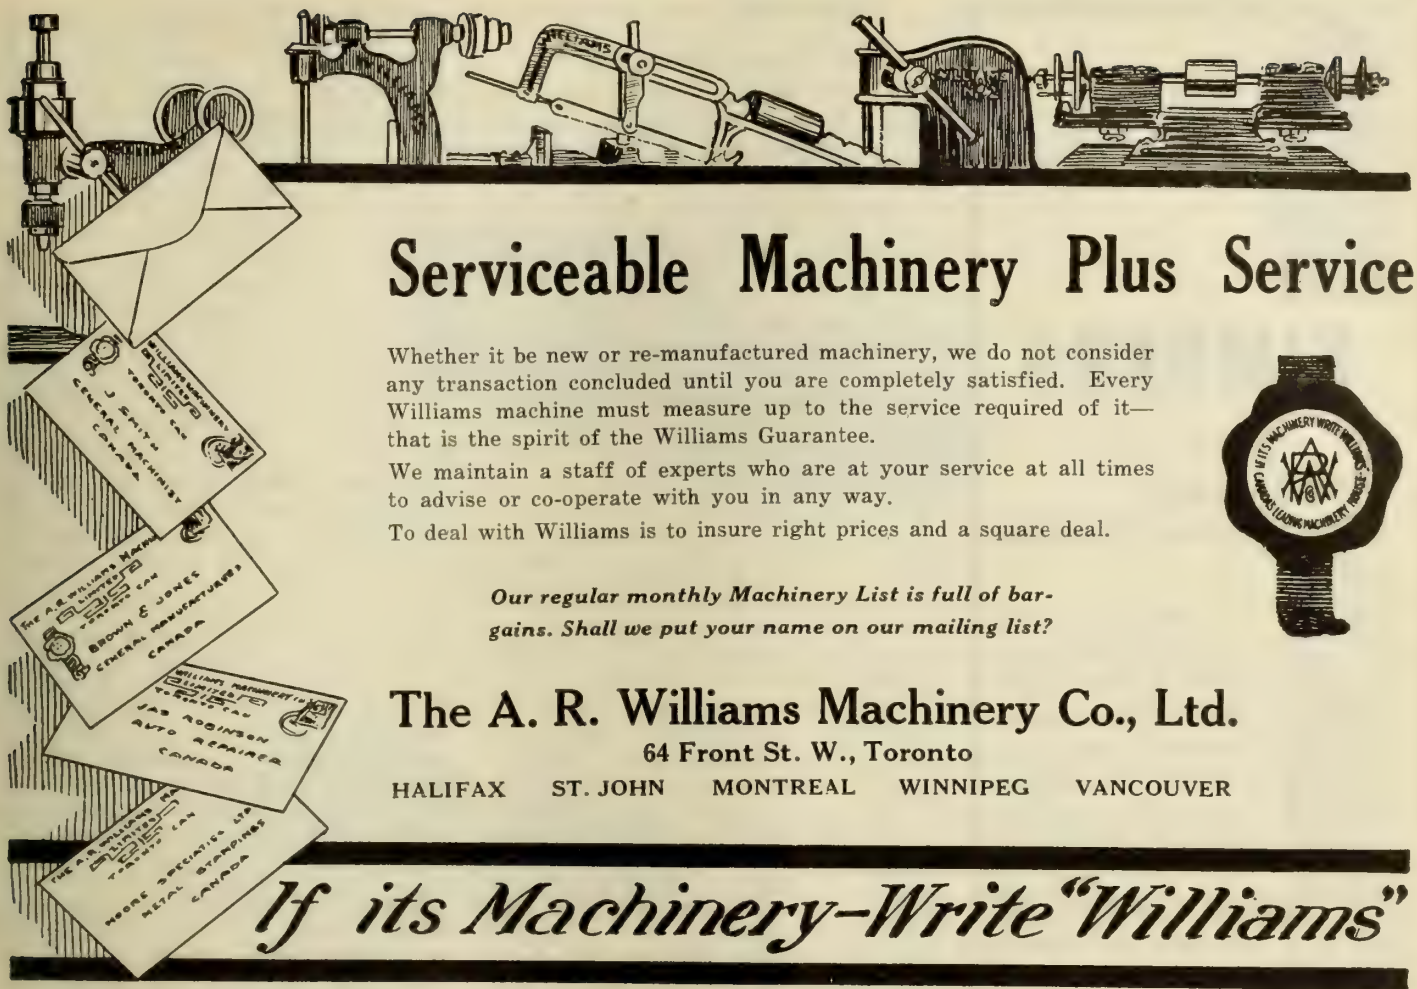
The city of Hull is installing a new 450 h.p. motor at the Hull waterworks plant on Brewery Creek. The new motor replaces a 300 h. p. motor that burnt out some time ago.

The Lion-Meade Rubber Co. is planning the erection of a large plant at Hull for the manufacture of tires, tubes and Meade valves. An option has been secured on six acres of land in Wrightville, a suburb. It is stated that the plant when in full operation will employ from 300 to 500 hands.

Carelton County Council has decided to delay the building of the proposed addition to the court house until such time as a better understanding has been reached with the city in regard to the length of time the city will continue to pay its share of the new buildings.

The John R. Booth Co. is building a new chimney stack which when completed will be the tallest in the city. The new stack, work on which has already commenced, is to be 267 feet above the ground and eight feet underground. The base, constructed of concrete will be 22 feet square and fifty feet high. Above will be 217 feet of brick masonry, the inside diameter will be 11 feet, 6 inches.

When purchasing high speed annealed steel it is always advisable to order sizes large enough for the removal of the outer surface, which may be slightly decarbonized. Scale and decarbonized surfaces should always be removed before hardening as a "soft skin" may result on the finished tool.



Serviceable Machinery Plus Service

Whether it be new or re-manufactured machinery, we do not consider any transaction concluded until you are completely satisfied. Every Williams machine must measure up to the service required of it—that is the spirit of the Williams Guarantee.

We maintain a staff of experts who are at your service at all times to advise or co-operate with you in any way.

To deal with Williams is to insure right prices and a square deal.

Our regular monthly Machinery List is full of bargains. Shall we put your name on our mailing list?

FUNDAMENTALS OF MILLING

(Continued from page 18)

ally at 350 inches, a third run gave 1,950 linear inches of metal cut.

Increasing the Feed

We then increased the feed per tooth to see if at this speed a higher feed would be beneficial. This run was made at a feed of .004 inches per tooth, speed 470 ft. per min., table travel 43 inches per min. We were able to cut only 1,365 linear inches of metal before dulling the cutter. This helped to prove our theory that the increased feed did not help to reduce the rubbing time but increased the deflection of the arbor. To carry this further we used a 9-tooth cutter at a speed of 400 ft. per min. with a feed of .0053 inches per tooth. We cut 2,145 linear inches of metal. This increase was due to the reduced speed. A second test under the same conditions gave only 860 linear inches of metal cut. That drop may have been due to bad stock because the cutter seemed to go bad at the start.

Our next run was made with the 18 tooth cutter at 370 r.p.m. or 290 ft. per min., and a feed of .119 inch per rev. or .0066 in. per tooth, table travel 44 inches per min. The cutter removed 2,920 linear inches of metal before it was taken out, and it was only slightly dulled. This increase was due, no doubt, to the decreased speed. But comparing this with our first test, we see that in spite of the great decrease in surface speed we have increased the life of the tool but very little. This, apparently, is due to the great increase in feed per tooth which has caused a greater deflection of arbor and consequently increased the time the tooth was rubbing on the stock. We had also increased the time the tool was in the stock cutting. A larger arbor would have helped to eliminate some of the rubbing at this high feed. However, the strain on the machine at this feed and speed was considered to be excessive.

We then reduced the feed per rev. to .072 inch making the feed per tooth .004 inch and the speed was increased to 520 r.p.m., or 410 ft. per min. Under these conditions we cut 2,728 linear inches of metal—about the same as at lower speed and higher feed. The results of the test are shown on the accompanying chart.

CANADA MAY SECURE MORE BRITISH CAPITAL

There is little doubt but that British industries will gradually come to Canada in larger numbers as did those from the United States, as British manufacturers come to realize the enormous benefits of manufacturing in Canada and achieve a more even balance between British and American houses prosecuting their activities in the Dominion. From all indications it is beyond conjecture that voluminous placements of British capital in various phases of Canadian development will take place in the near future, and that the movement will expand with the progress of time and the brightening of conditions. The rise of sterling, the prospect of rosier economic times, the realization of the necessity of meeting competition on the ground of the opponent, are all combining to centre in Canada an interest which wavered merely from force of circumstances. There is no reason to suppose that United States interest in Canada will ever decline—the tendency would certainly seem to be for this to increase—so that with capital coming, in addition, in substantial amounts from the British Isles and vieing with that from across the border, Canada should prosper exceedingly from the business rivalry and experience a period of development surpassing anything she has hitherto known.

T. A. Hollinrake, general manager, A. R. Williams Machinery Co, Toronto, has returned from a trip of several weeks to the Maritime provinces. His impressions, as to the industrial outlook in the East are optimistic. Building activity and conditions generally indicate that that part of the Dominion is keeping pace with a steady trend toward normal.

Truro, N. S.—On July 15 the planing and woodworking mill of McCullough Bros., Debert Station, about 12 miles from this place, was totally destroyed by fire. It is stated that there was no insurance on the mill.

Montreal.—It is announced that the Dominion Bridge Co. has secured four contracts for the steel bridge superstructures which are to be erected by the Public Works Department of the New Brunswick government. The sum of four contracts is understood to be in the vicinity of $40,000.

Montreal.—The Montreal Board of Trade plan to celebrate the one hundredth anniversary of that institution by taking a seven thousand mile trans-Canada tour by a special route embracing lake, rail and ocean. An offer is being made to British members of parliament to join the tour, and reports indicate that between twenty and thirty of them will avail themselves of the opportunity. The party leaves Montreal on the evening of September 1st, by Canadian Pacific Railway going to Toronto, thence to Port McNicoll where a lake steamer is boarded. At the twin cities, Port Arthur and Fort William the rail journey is resumed. Travel by C. P. R. continues to Vancouver and Victoria, the Canadian National coastwise steamer is boarded for a trip to Prince Rupert. A Canadian National train is here boarded and the party returns to Montreal entirely on the National System, arriving on Saturday morning, September 30th.

4,000 Threads in One Day

With a Geometric Threading Machine a thread .891″ Diam., 32 pitch, V, 7-16″ long, is cut on 4,000 Graphophone Brass Mouth Pieces in one day. Before the work was put on a Geometric Threading Machine, a solid die was used, and, with the necessary backing off, only 800 pieces could be threaded in one day.

Geometric Threading Machines give production increases that mean much.

Send for the booklets.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

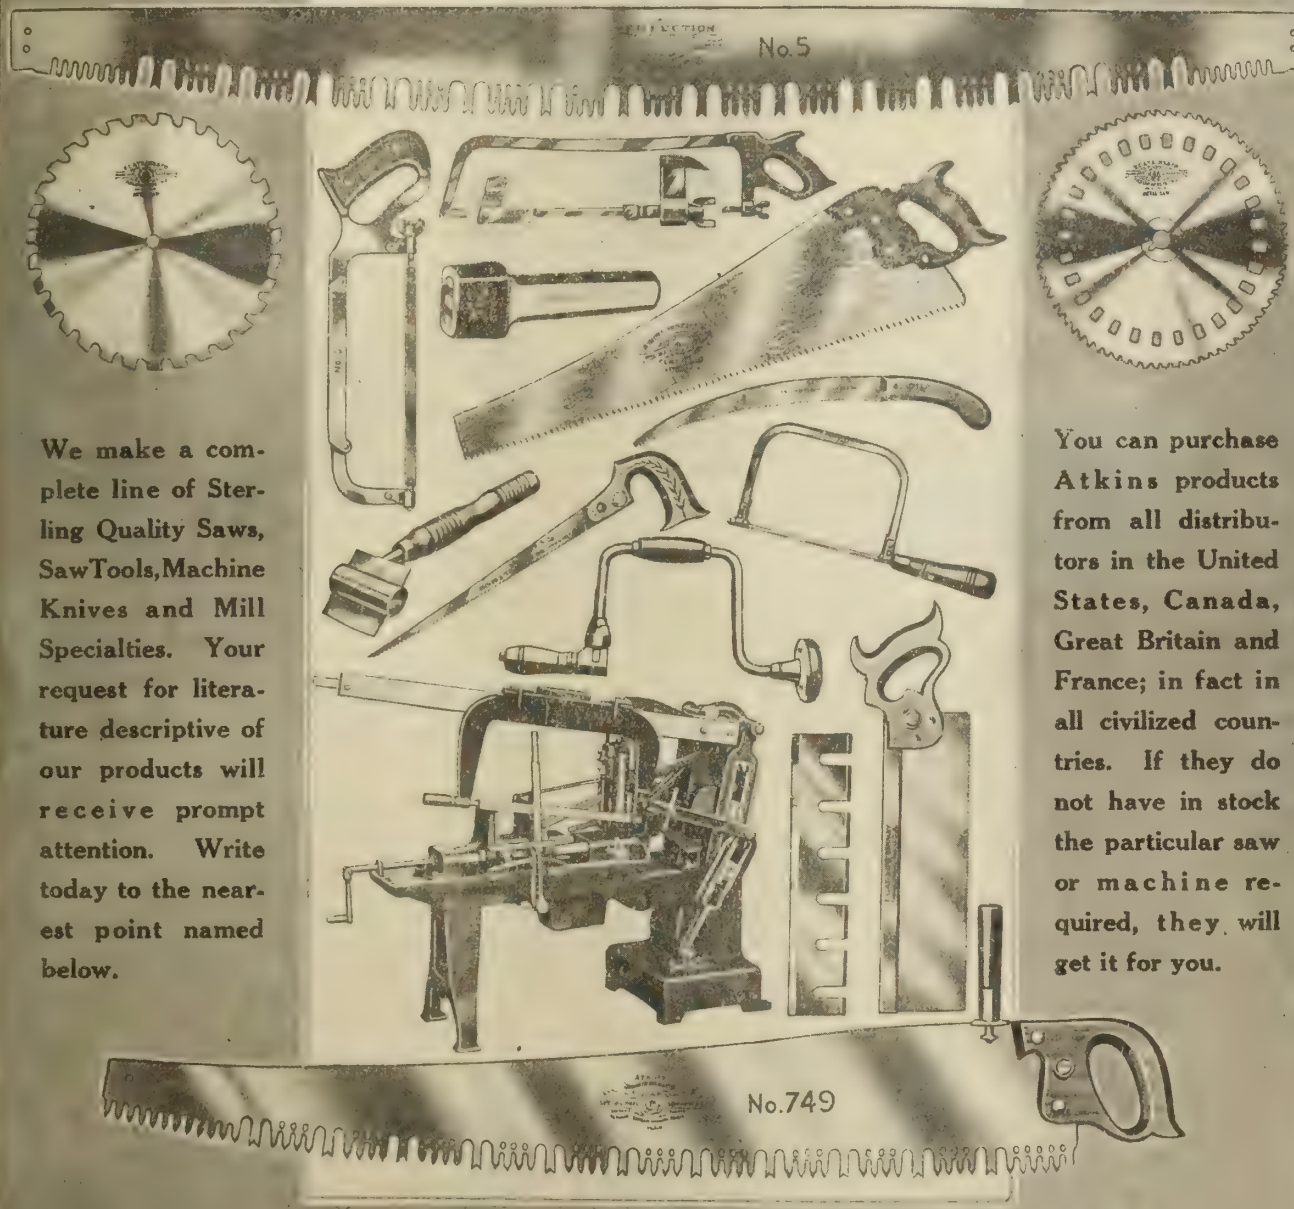
STERLING QUALITY SAWS and TOOLS

A Perfect Saw for every Purpose

"Finest on Earth"

"Finest on Earth"



We make a complete line of Sterling Quality Saws, SawTools, Machine Knives and Mill Specialties. Your request for literature descriptive of our products will receive prompt attention. Write today to the nearest point named below.

You can purchase Atkins products from all distributors in the United States, Canada, Great Britain and France; in fact in all civilized countries. If they do not have in stock the particular saw or machine required, they will get it for you.

If you have difficulty in obtaining Atkins Saws and other products through your regular service, write

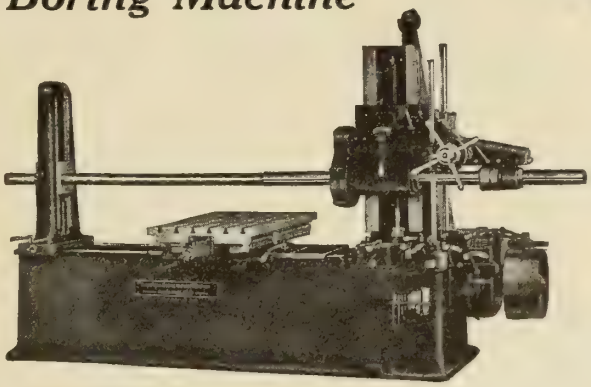
H.W. PETRIE LIMITED

Canada's Dependable **Machinery and Supply House**

The Universal Horizontal Boring Machine



This machine is designed for Boring, Milling and Facing. It helps, and frequently takes the place of, the Lathe, Planer, Drill and Milling Machine. The nine feeds are entirely independent of the sixteen feeds. Let us send you full particulars.

Bring Your Machinery Problems to Us!

FOR fifty years we have been adding to our facilities for handling machinery of all kinds. For fifty years we have been sustaining confidence as Canada's leading machinery firm! For fifty years we have been growing! One force, more than others, is responsible. That one is

Service

This service means that the Petrie staff takes a minute interest in the requirements of every customer; it means that the customer gets what he orders—further, Petrie service includes advice on the selection of proper equipment and advice on the solving of all machinery problems that frequently come up in the machine and woodworking shops.

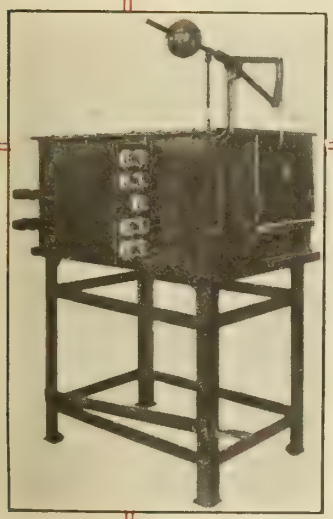
CANADIAN MACHINERY
AND MANUFACTURING NEWS

Vol. XXVIII. No. 4 Published Weekly by the MacLean Publishing Company, Limited, Toronto, Ont. July 27, 1922 $4.00 a Year Subscription Price

READ AND PASS TO	Check	See Page	READ AND PASS TO	Check	See Page



Kleer-Heet electric furnace for preheating extra long planer knives—a typical example of Kleer-Heet quality and design.

The adaption of Kleer-Heet electric furnaces to the tinning, galvanizing, annealing and heat-treating of wire, the porcelain enameling of bath tubs and bathroom fixtures, the baking of cereals, enamels and electrical apparatus and the general heat-treating of steel of all kinds has brought to the attention of Canadian manufacturers the superiority of electricity as a heating medium for many operations.

Units easily replaceable while the furnace is in operation, muffles practically unbreakable, and efficient heat insulation, makes the Kleer-Heet electric furnaces compare favorably with gas, oil and coal as to operation costs and reliability and with maintenance costs and quality of the finished product much better.

Our engineers will welcome the opportunity to work with yours on your heating operations.

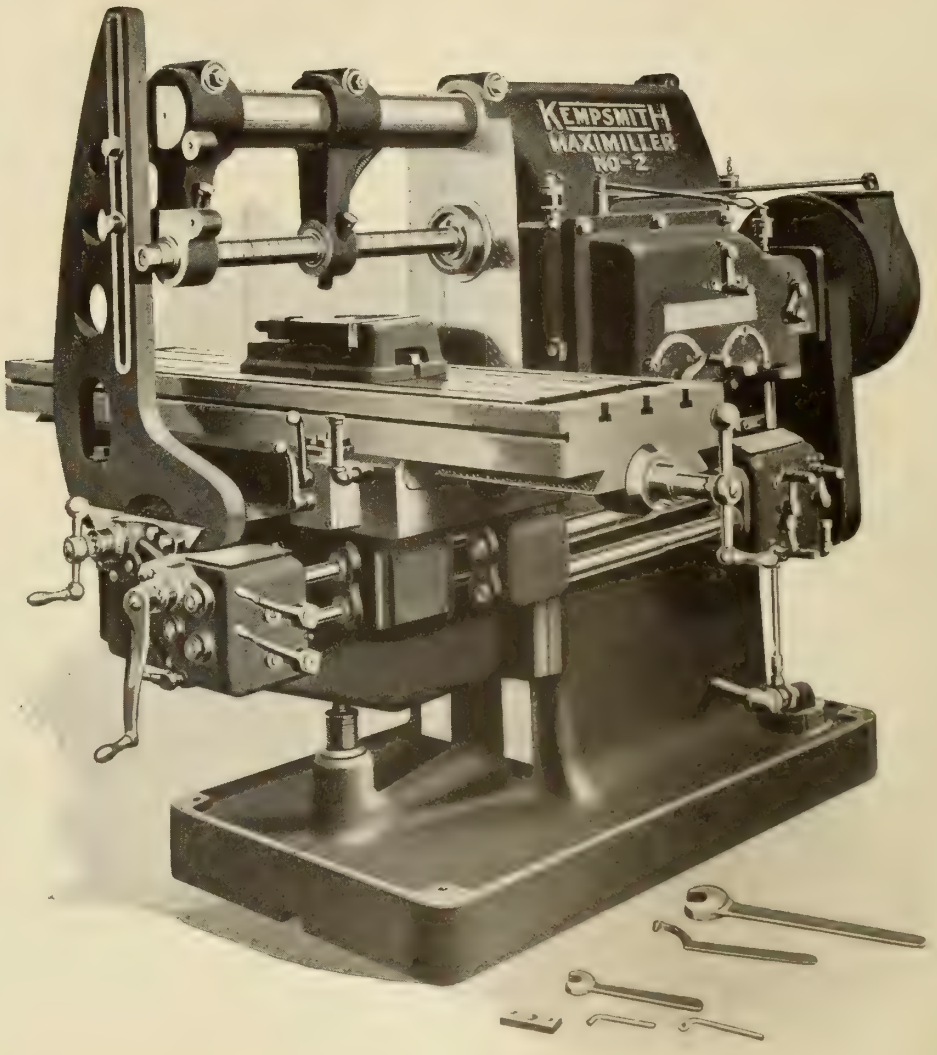
KEMPSMITH



NO. 2 PLAIN MAXIMILLER

Kempsmith Millers are built in three sizes each in the Plain and Universal Cone Types, two sizes of Maximiller Geared Head Types, a Production Type, with a choice of three table ranges, and two sizes of Vertical Geared Head Type. Our Knee Type Millers can be fitted with a complete line of attachments, which greatly increase the range of the milling machine.

Literature will be gladly sent upon request.

Merit Keeps Them On The Job

ON HEAVY tapping like this, P & W Staybolt Taps show their quality. They bite into the work with a precision and ease that makes them favorites with the men who use them.

They are not only good when new, but are heat treated and seasoned to maintain this goodness. That's why you'll find them still on the job when others "just as good" are in the scrap pile.

PRATT & WHITNEY STAYBOLT TAPS

To meet all your boiler requirements, we build P & W Staybolt Taps in five standard styles, as well as Spindle Staybolt Taps with and without threaded end and also Combined Reamer and Tap to tap continuous hole in the reamer hole of the far boiler plate.

Our reputation for precision and high quality stands behind these tools. Buy them in any of the styles and sizes listed in our Small Tool catalogue which is yours for the asking.

These taps and our complete line of Small Tools are on sale at our offices in Boston, Philadelphia, Birmingham, Rochester, Cleveland, Detroit, St. Louis, Cincinnati, Seattle, St. Paul, New Orleans, San Francisco.

DIAMOND FIBRE

Condensite Diamond-F Celoron

The application of DIAMOND FIBRE to the industrial field is practically unlimited. Thousands of parts are being made daily in the Electrical, Mechanical, and Transportation fields alone, where DIAMOND FIBRE plays an important part.

The properties of this material make it an ideal insulation medium, and so varied and widespread is the use of DIAMOND FIBRE for machined parts and special parts for electrical and mechanical purposes, that it is impossible to list and classify each use.

Write us and we will tell you how to use DIAMOND FIBRE to advantage in your business.

CONDENSITE CELORON is an ideal material for both the RADIO AND ELECTRICAL industries. Being so high in insulating quality, plus hard waterproof in character, it is the very best material obtainable for instrument panels, dials, knobs, rheostats, condenser bases and other similar parts.

CONDENSITE CELORON can withstand high voltages and currents without difficulty and there is practically no piece of radio apparatus where it cannot be used to advantage.

For prices and full data on both these products write to the

Diamond State Fibre Company

Effective Co-operation

THE three newspapers you see illustrated here belong to the MacLean Technical Group.

If you are a manufacturer of equipment that can be used in machine shops, metalworking plants, power plants, or foundries, one or all of these papers can give you effective cooperation in increasing sales. Tell the consumer about your products in the columns of these publications. The men who buy industrial equipment read them. Your products may have advantages over other products of their kind. Tell the consumer what they are. Create a desire in his mind to buy your lines when ordering from the dealer.

An effective message in MacLean Technical Newspapers will prove effective cooperation for the promotion of sales, and the group you can use to greatest advantage includes:

CANADIAN MACHINERY
AND MANUFACTURING NEWS

POWER HOUSE

CANADIAN FOUNDRYMAN
AND METAL INDUSTRY NEWS

Canadian Machinery serves the iron and steel and general metal working industries.

Power House serves steam, electrical, water and gas power plants.

Canadian Foundryman serves the grey iron, steel and non-ferrous foundries.

Each of these papers covers their respective fields almost exclusively. They are "Canadian National" in scope and are read by the men you are anxious to reach—proprietors, managers, superintendents, purchasing agents and foremen. Attract the attention of these men with a strong appeal in their favorite technical newspaper—the MacLean service staff will assist you.

GRUNDY Patent Flexible Insulated COUPLING

THE IDEAL COUPLING
For Direct Connected Drives
Perfect Insulation and Flexibility

Coupling is constructed of 3 pieces only. Its simplicity ensures ease in installing and satisfactory operation.

Designed to correct errors in alignment of bearings it is extremely satisfactory where perfect alignment is hard to get or where bearings are liable to get out of adjustment.

Grundy Couplings will transmit more Horse Power than any other flexible coupling of equal diameter. They are perfectly balanced and adapted for revolving at high speeds.

Especially recommended for connecting motors to pumps, machine tools, sewing machines, wood-working machinery, printing machinery, fans, blowers, etc.

Our booklet ECM is fully illustrated and contains full engineering data. Send a post card for it to-day.

Style A: 30-degree Angle Valve, sizes: ½" and ¾". Inlets and Outlets are Standard Pipe Thread.

Style RA: 90 degree Angle Valve sizes ¼" ⅜" ½" and ¾". Inlets and outlets are standard pipe thread.

Style RA

Styles A, RA and SL have waste-ports to bleed air from hose.

Style SL

Style SL: The inlets and outlets are the same size and in alignment. Sizes ¼" ⅜" ½" ¾" 1" 1¼", 1½" and 2" standard pipe thread.

IN STOCK

Riveting Hammers, Chipping Hammers, Sand Rammers, Air Drills, Grinders, Corner Drills, Bowes Hose Couplings, Cleco Air Valves, etc.

Style F.W.L.: Four-way valve controls the supply and exhaust from both ends of a double acting piston. Sizes: ⅜" ½" ¾" and 1" outlets.

Write for Illustrated Bulletin No. 50

The Air Pressure is always on the Large end of Valve Plug holding it firmly on Seat.

The Valve That Improves With Use
Requires no attention after installation.

Style FWL

Style LW

Style LW: Three way valve sizes ½" ¾" and 1." Outlets standard thread.

For Making Perfect

Screw - Thread Joints

SMOOTH - ON

ELASTIC CEMENT NO. 3

A screw-thread joint made with Smooth-On Elastic Cement No. 3 will not leak, because the Smooth-On expands in metallizing and so closes up any defective places which otherwise would cause leaks; yet the joint may be taken apart when desired.

Smooth-On Elastic Cement is sold ready for use in paste form. It is applied to the screw-threads with a brush. Especially useful for high pressure steam or water joints, for ammonia joints, for coating flanged joint faces and for coating gaskets.

Send for our new Smooth-On Instruction Book No. 18. It illustrates and describes how to make perfect screw-thread joints and hundreds of other repairs. You will marvel at its contents. The book is FREE.

BROWN & SHARPE UNIVERSAL GRINDING MACHINES

In Constant Use Wherever Installed

For the Small Shop

The Small Shop with a varied assortment of work should consider the wide range of usefulness of Brown & Sharpe Universal Grinding Machines. In addition to ordinary straight or taper grinding, these machines do internal grinding, grind tools, cutters, and the sides of circular saws, etc. The adaptability of these accurate machines should appeal to the owner of the growing shop. The busy shop with a wide variety of grinding is just the place for one of these useful machines.

For the Large Shop

The Large Shop will find the high quality and general usefulness of Brown & Sharpe Universal Grinding Machines warrant serious consideration. Their sturdy construction makes them suited to production work. During the intervals between production jobs their adaptability to all types of grinding keeps them constantly occupied. Add these machines to your grinding equipment. Their accuracy and durability make them investments of the highest value.

Canada Rich in Electrical Power

IN CONSIDERING any phase of electrical development, it seems impossible to avoid a comparison of conditions at the present time with what they were, say thirty years ago. Street illumination by arc lamps then represented the extent to which it was known, in a general way, as a public utility. Its application to the hundred and one purposes by which it has become familiar to-day, was then quite a matter of theory, and it is even doubtful if those whose knowledge could then boast a certain amount of intimacy, were even inclined to prophesy as to the scope of its industrial objective.

The development as represented by the electrification of street and former steam railways, has of itself outstripped imagination while the almost universal use of the motor in all branches of industrial activity is one of the most wonderful illustrations of 20th century adaptability.

Electricity may be said to symbolize economy in a sense not formerly applicable to that word. It has contributed immeasurably to high efficiencies wherever introduced, has given increasing scope to enterprises of every kind so that industrial populations have benefited and standards of living much improved.

A Fortunate Position

Canada is in a fortunate position as regards electrical development. To-day approximately 3,200,000 developed horse power represents the extent to which the country's hydraulic resources have been converted for public utilities and varied industrial purposes. But even this does not represent the whole story. The limit of this wealth is not even within sight. There is some significance for Canada in the recent statement of an eminent scientist that "at some time more or less remote—long before the exhaustion of our coal—the population will gradually migrate to those countries where the natural resources of energy are most abundant."

With the single exception of Norway, Canada is the second nation of the world as regards horsepower available and horsepower actually developed per capita of population. It is estimated that this country has 19,000,000 available horsepower or 2.21 per capita and .26 developed. The figures for Norway are 55,000,000 available or 2.29 per capita and .54 developed. The United States has 30,000,000 available horsepower or .28 per capita and .07 developed. The completion of the gigantic work undertaken by the Ontario Hydro-Electric Commission is making available 500,000 horsepower of electric energy. Apart altogether from the benefits to be derived from the ultimate distribution of power the expenditure of something like sixty millions of dollars must benefit a large part of the community, from the farmer who sold the land through which the power canal passes, along to the laborers, artisans, mechanics, engineers and manufacturers of all kinds of equipment, electrical and otherwise. This is the outstanding example of such development in Canada, and it must make its appeal to industrial growth.

Boon to Industry

The flexibility and economy of electric power is the explanation of its demand, whether it be applied for transportation purposes, industrial operation or domestic services. It is immediately available at all times. Discoveries as to its varied uses are so frequent that none will be so venturesome as to measure its scope. Medical men declare that, as a factor in dealing with certain ailments, its possibilities are wonderful, while upon its potentiality have been built up great achievements in connection with wired and wireless communication. It has revolutionized certain tool room and heat-treating methods, it is being applied with great success in the smelting and treatment of metals, it has been so employed as to immeasurably improve working conditions in many industries, it is saving time, energy and money in countless ways. While contributing much to those things which make life worth living, those who know most about it declare that things electrical are still in their infancy. Already its triumphs have been stupendous: it is the electrical age.

Electric Steel Furnace Development in Canada

Proven in 1906 That Canada Ores Can Be Successfully Smelted —Initial Difficulties Ironed Out—Incentive to Production of Certain Alloy Steels—Recognized Part of Modern Steel Plant

By J. Young, Volta Mfg. Co.

THE advent of the first electric steel furnace in Canada might be traced from the time the Canadian Government named a commission to investigate the possibilities of using electric power for the reduction of our native ores. A furnace for this purpose was installed at the Canadian Soo in the year 1906, and the results obtained showed that Canadian ores could be successfully and economically smelted. Dr. Heroult and R. Turnbull were the designers of this furnace, and, immediately after completing this initial test for the Canadian Government, they designed and installed the first of the famous Heroult type electric steel furnaces—this first furnace being built and used in the States.

Early Difficulties

In the first furnaces built the designers were faced with many serious difficulties and had to be possessed with an abundance of courage and perseverance. Owing to the high temperatures at which electric steel furnaces operate, much of the standard equipment, at that time, was not suitable; refractories, which would stand up any length of time, were difficult to get, while the standard electrical insulations, used on furnaces at that time, were continually breaking down on account of the heat; mechanical parts, of standard design, were found unsuitable to stand the conditions peculiar to electric furnaces. Then, there were the electrodes to contend with. Electrodes of only a small size were made at that time, and a good deal of experimenting and research work had to be done before electrodes, that would stand up a reasonable length of time, could be obtained.

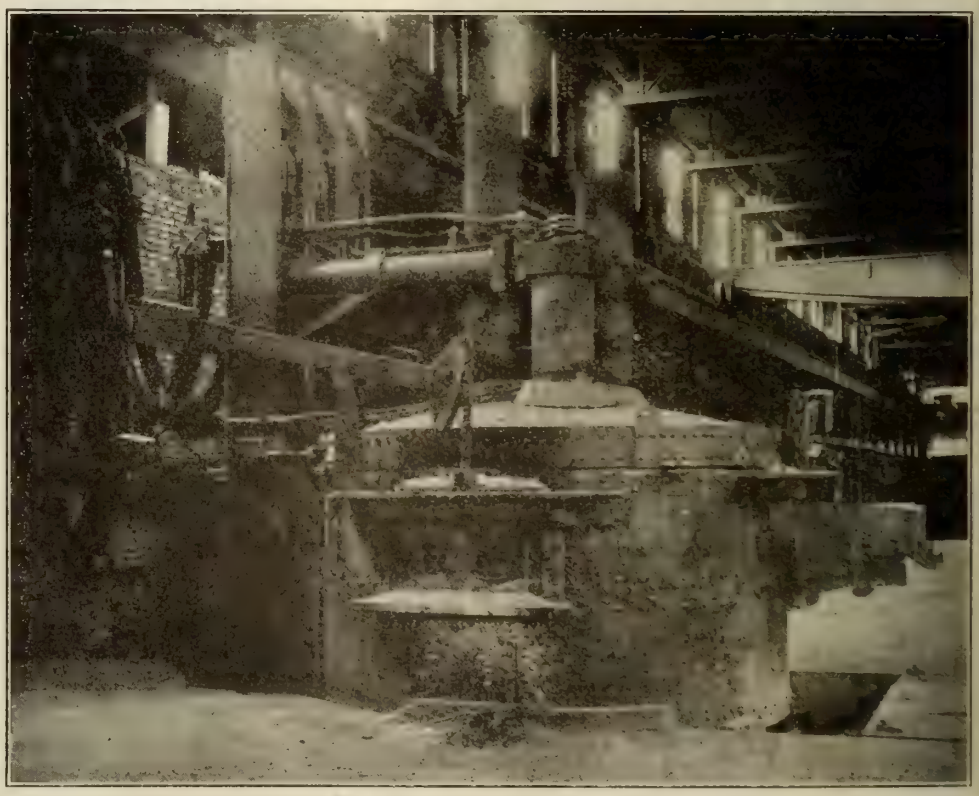
These initial difficulties, however, were gradually ironed out and the electric steel furnace then began to assert itself. The steel men became interested in it for several reasons. It had been proven, conclusively, that electric steel had properties which could not be got by the other methods of making steel; it could be produced economically, and it presented the only means of making the special alloy steels which were necessary in the automobile industry, with the result that installations began to appear in various parts of the country and these furnaces were giving highly satisfactory results when the war broke out and an added impulse was then given to their use. Canadian Steel Companies, whose limited market up to that time caused them to hold back, then began to instal electric furnaces with the result that by the year 1919 there were at least 40 electric steel furnaces in operation in Canada, capable of producing over 200,000 tons of steel per year. The British Forgings, Limited, of Toronto, Ont., had in operation a battery of ten 6-ton capacity Heroult type furnaces, which was, at that time, considered the largest installation of electric steel furnaces in the world. Since the termination of the war the number of electric furnace installations have been continually added to with the result that there are, as far as the writer's knowledge goes, approximately 50 furnaces installed in Canada at the present time.

Causes of Failure

As I have previously stated, the electric furnace, in the steel industry, is now a recognized part of a modern steel plant. There are, however, instances where the electric furnace has not been a success. These failures can, in many cases, be traced to an over-zealous salesman, who, in his ambition to make a sale, has not taken into full consideration the local conditions, or, again, it may be due to poor operation. The electric furnace cannot be operated, to give the best results, with any sort of mediocre operation—in fact, as in all other businesses, a man thoroughly acquainted with his work will give better service than the one who lacks experience. I heard the statement made that it just cost a certain party $10,000 to find out that electrical steel castings were not sound and could not be depended upon. To those conversant with electric steel furnaces such a statement would not be taken seriously, as it has been amply proven that electric steel castings are superior to either open hearth or converter castings. On the other hand, such statements tend to check bona fide sales.

I stated that during the war the electric steel furnaces established their place in the steel industry. In one forging plant, where a complete record was kept of the different steels used for shells, and where the blanks came from diversified sources, those made by the electric process showed less rejects and superior physical qualities in every way as well as more consistent chemical analysis. I do not mean to say that the electric furnace will take the place of other methods of making steel. It has its place as a steel producer, and, where installed with proper judgment and operated by efficient men, will give satisfactory and highly efficient service.

Of late, manufacturers of grey iron castings have turned their attention to the use of the electric furnace for mak-



Six-Ton Heroult Type Electric Furnace

ing grey iron in order to meet the ever-increasing demands for high quality grey iron castings, and several furnaces have been installed to produce grey iron for the making of cylinders, piston rings, etc., used extensively in the automobile business.

In Canada, however, where electric power is comparatively cheap in many localities, the electric furnace not only is a competitor with the cupola on a quality basis but also on a cost basis for ordinary castings and furnaces are in operation in Canada, producing electric grey iron for castings, continuously.

The electric furnace differs from the cupola in this respect, that it offers a larger range of products on account of the fact that the analysis of the finished article can be controlled within a very fine degree. Furthermore, a dual system is in use in some places—and is working out successfully—where steel and grey iron is produced from the same furnace.

A list of steel and pig iron electric furnaces installed in Canada follows:—

Quebec

Armstrong, Whitworth of Canada, Ltd., Montreal, one 3-ton and 3 6-ton "Heroult" type furnaces.

Canadian Electric Steel, Limited, Montreal, three 7-ton modified type "Heroult" three-phase furnaces.

Canadian Brakeshoe Company, Sherbrooke, Que., one 1-ton and 3 2-ton furnaces.

Canadian Steel Foundries, Ltd., Montreal, one 1-ton "Volta" Heroult type, 3-phase "quick-melting, or duplex voltage" furnace.

Thos. Davidson Mfg. Co., Ltd., Montreal, four 6-ton T. D. Mfg. Co. 1 2-ton T. D. Mfg. Co. and 1 1½-ton Snyder furnaces.

Hull Iron and Steel Foundries, Limited, Hull, one 6-ton Heroult type, three-phase tilting furnace.

Joliette Castings and Forgings, Limited, Joliette, one 2-ton Greaves-Etchell furnace.

Shawinigan Foundries, Limited, Shawinigan Falls, one 5-ton "Volta" Heroult type, 3-phase, stationary type furnace.

Ontario

Baldwins Canadian Steel Corporation, Ltd., Toronto, ten 6-ton Heroult furnaces.

Baldwins Canadian Steel Corporation, Ltd., Collingwood, one 3-ton Heroult, stationary furnace.

Bowmanville Foundry Co., Bowmanville, one 1¼-ton Cronwall-Dixon.

Canada Electric Castings Co., Limited, Orillia, one 1½-ton, two-phase, tilting furnace.

Electric Iron, Limited, Lakefield, one 6-ton "Volta" 3-phase, tilting furnace.

Dominion Foundries and Steel, Ltd., Hamilton, two 6-ton "Volta" Heroult type, 3-phase, tilting furnaces.

Electric Steel and Metals, Limited, Welland, one 6-ton Heroult, 1 7-ton Heroult.

Electro Foundries, Limited, Orillia, one 6-ton "Volta" 3-phase, pig iron furnace, one 6-ton "Volta" 3-phase, Ferro-alloy furnace.

Tivani Electric Steel Co., Limited, Belleville, one 2-ton; one ½-ton, and one 1/3 ton.

Turnbull Electro Metals, Limited, St. Catharines, one 6-ton "Volta" stationary, 3-phase, pig iron furnace.

Manitoba

Manitoba Steel Foundries, Ltd., Winnipeg, one 2-ton, single-phase, one 2-ton, three-phase, furnaces.

British Columbia

Port Moody Steel Works, Ltd., Port Moody, one 6-ton "Volta" 3-phase.

Lowox Steel Company, Ltd., Vancouver, one 6-ton, 3-phase "Volta" stationary type, furnace.

Opsal Steel Company, Vancouver, one 2½-ton, three-phase, tilting furnace.

Shipton Electric Pig Iron and Steel Smelting Co., Limited, Vancouver, one 1-ton furnace.

Vancouver Engineering Works, Limited, Vancouver, one 1-ton Greaves-Etchell furnace.

For Export

Union Electric Steel Company, Carnegie, Pa., two 6-ton "Volta" Heroult type, 3-phase, tilting furnaces.

T. Waddell & Sons Company, Limited, Christchurch, New Zealand, one 6-ton "Volta" Heroult type, 3-phase, tilting furnace.

Renton & Fisher, Limited, Hopetown Steel Works, Bathgate, Scotland, one 3-ton "Volta" Heroult type, 3-phase, tilting furnace.

Electric Furnaces for Non-Ferrous Metals

THE adoption of electric furnaces for melting non-ferrous metals has been a significant factor in Canadian non-ferrous foundry development during the past year. The list of installations of these furnaces in Canada now embraces practically all sizes from five hundred pounds up to two thousand pounds, while some Canadian foundries are already increasing their original installations by adding additional furnace units.

Greater ease and economy of operation are responsible for this change in furnace equipment. Foundries generally are seeking to better the quality of their castings and reduce the percentage of rejections, and so are turning to electricity as a sure method of producing non-ferrous castings entirely free from porosity and gas occlusions.

Installation at Dom. Steel Products Co., Brantford, Ont.

Electric melting also cuts the metal loss to less than one per cent. and there is a considerable labor saving over fuel furnaces, because one man can tend a whole battery of electric furnaces; and if but a single furnace is employed, he is available part of the time for other duties in the foundry.

Plenty of Power Available

Power rates in Canada also form a strong inducement, representing a saving which is not available to most brass melters in the United States, where hydro power is not available.

The chief type of electric furnace for non-ferrous work installed in Canada has been the Baily resistance type. Each furnace equipment consists of a transformer, switch and furnace proper, designed to work together upon a very simple and practical principle. The transformer takes current at any high tension voltage up to 22,000 volts and steps it down to the relatively low voltages required by the furnace. Nine low tension voltage taps are brought out from the transformer to a selective oil break switch. The current passes from the switch through two carbon troughs into a circular trough within the furnace.

(Continued on page 25)

Electric Trucks Help Solve Factory Costs

Reliable Utility Factor in Indoor Transportation—Development Suggested By Crude Methods in Handling Fruit—Easy of Operation—Reduces Cost From 50 to 75 Per Cent.

By R. F. HIBBARD

IT IS twelve years since the first industrial electric truck made its appearance and Buffalo is credited with being its birthplace. It was designed and built to aid indoor transportation of all kinds of merchandise heretofore handled by hand trucks. Its success was assured from the first, but its adoption for indoor use was immediately extended to any and all places where anything better than a corduroy road was available.

The industrial electric truck has been going through the development period. Experience has shown its few shortcomings and the necessary changes to produce efficiency under varying conditions. Each year has brought about such improvements as have placed this vehicle for indoor transportation on a par of perfection and utility with the automobile truck as a time and labor saver.

When W. H. Wright, of Phelps, N. Y., called on a friend who had charge of the Erie R. R. piers in Jersey City, some thirteen years ago, he had an opportunity to study the rather crude methods that were then in vogue in transportation on docks in general. Much fruit was spoiling because of lack of means to handle it quickly. The condition was so far regarded as beyond remedy that it was looked upon as a necessary evil. That is where the idea of an industrial truck had its birth.

Trucks Solved Problem

Returning to Buffalo, Mr. Wright secured a discarded motor, a differential link roller chain, silent chain and various other miscellaneous items and from these he built his first industrial electric truck. This was known as a carrying truck. It was necessary to place the load upon it for transportation purposes. It had chain drive, two-wheel steer, platform 6 feet long, height of platform 20 inches, width of truck 40 inches, 24-volt motor, speed, empty, 6 miles per hour, speed loaded, 4½ miles per hour, capacity 4,000 lbs.

The author is president of the Wright-Hibbard Industrial Electric Truck Co., Phelps, N. Y.

This truck, when completed, was sent down to the docks at Jersey City to be tried out. The result was that the truck solved a serious problem. Shortly after this the Erie placed an order for 20, and found in time that they would do the same work that had formerly required 130 men, and it was not long afterwards that they came into general use for this kind of work for railroads, steamship docks, warehouses, etc.

Loaded Truck Going Up an Incline

After the carrying truck was on the market for a matter of 2 years, further developments in the electric truck transportation, brought out the industrial electric truck, which is used for large docks, industrial plants, for pulling trailers loaded with merchandise, etc. As many as 6 or 8 trailers are pulled with these tractors at one time. Where these tractors have long pulls and can be kept reasonably busy the labor cost of transporting materials can very often be cut 50%.

Trucks Serve Entire Warehouse

Further developments in electric truck transportation, brought out what is known as the 2-ton industrial electric raised platform trucks. Users of these trucks were required to purchase or make up wooden or steel platforms themselves, 30 inches wide, 53 inches long and 11 inches high. These platforms were placed in different positions throughout their plants or warehouses, etc. The material which was to be transported was placed on these platforms. When loaded, the electric ran under same and elevated it off the floor, approximately 4 inches and transported it to the R. R. cars, stockroom, or wherever required.

Most of these raised platform trucks have 4 wheel steer and are worm driven, equipped with 2 motors, 24 volt, one motor for driving the truck and one for raising the platform. Battery equipment consists of 21 or 24 A-6 Edison cells or 12 cells of 15 or 17 plate lead battery, weight approximately 2,600 lbs.

About six years ago a raised platform industrial electric truck, similar to the one mentioned above was developed. In this it was necessary to use but one motor, which both drove the truck and raised the platform. In other words, they used but one unit instead of two, which meant a lighter truck with fewer parts. It was proved beyond a doubt that these raised platform industrial trucks showed a saving of at least 75% in transportation cost over old methods of transportation.

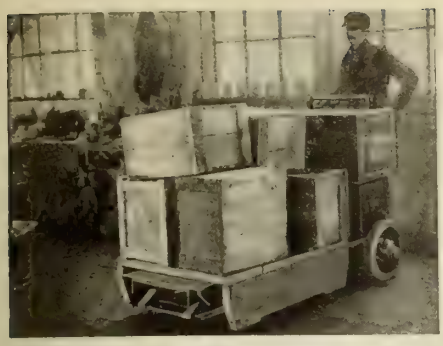
Efficient Small Trucks

The next development in electric trucks had to do with the idea that practically every firm in its infancy starts in with hand-lift trucks and small skids and at some time in its growth, it must change to the electrical unit in order to handle the volume and furnish the speed necessary to transport the product from one operating department to another. Such a change, it appeared, would involve, in some instances, thousands of dollars, but in response to the demand, such a truck made its appearance. It met the conditions as described and, as a matter of fact, does not require any more space in which to operate than does a hand-lift truck and at the same time uses all hand-lift truck equipment. This small truck will do anything that the larger ones would, and more, and sells for a great deal less. It is regarded as most efficient for all round work.

Taking Work from Drill Press

Operating in Store House

Taking a Load from Stock

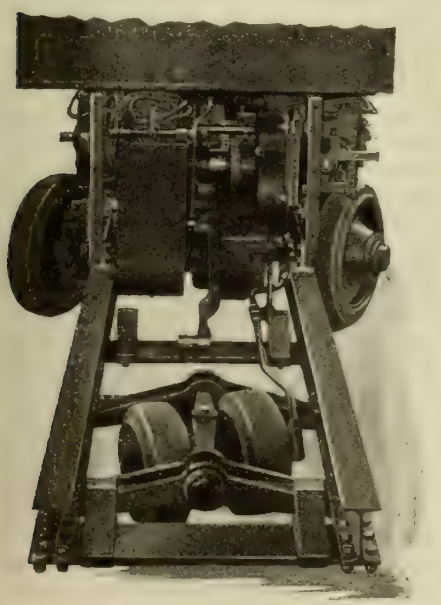


Transferring Loaded Cases

There are very few industrial plants that cannot use at least one of the above type of truck to good advantage, thus saving a considerable amount of labor cost in indoor transportation. As to what the amount of saving would be, depends entirely on the conditions under which the truck is operated. In some plants these trucks will do the work of 6 men and in many instances they are doing the work of 20 men.

Watch Transportation Costs

When the first industrial electric trucks were put on the market, it was necessary to demonstrate them in practically every plant that anticipated the use of same, for the reason that manufacturers did not as a rule know what their indoor transportation was costing them. They had always carried this important expense as miscellaneous or overhead expense; therefore they did not realize, that, if one of these trucks would do the work of only 2 men, this reduction of transportation expense would in itself pay for the truck in less than one year's time. However, manufacturers were quick to realize this important addition to their plant equipment and today these trucks are looked upon as an absolute necessity by the majority.



Constructional Features of the Truck

Adapt Direct Electric Drive to Various Production Needs

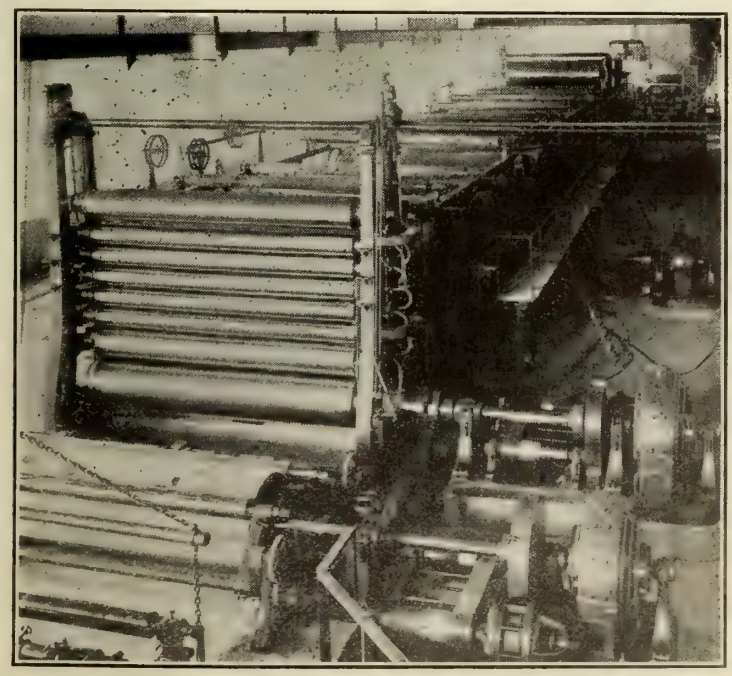
DIRECT electrical drive for various industrial purposes has claimed recognition because of its economy, reliability and efficiency. One advantage claimed for it is that the power plant, whether steam or water-driven, may be so placed as to obtain the greatest economy in the generation of power without regard to the location of the manufacturing plant or the equipment to be operated. The point of production may therefore be selected where most advantageous for receiving or shipping purposes. Building costs may be kept down by reductions in installations for mechanical drive. Handling of the product may be facilitated by location of motor-driven machinery to best suit requirements of routing, and where numerous motors are used any machine or group may be stopped without interfering with the remaining machinery. Defects in transmission are easily traceable and motors may be adjusted to speeds to give best results. The flexibility of electric drive is also illustrated by the fact that additions to plant may be made without interference with original equipment.

Whether alternating or direct current is used, depends upon the requirements of the equipment to be operated. A large percentage of machinery operates at constant speed and as the alternating current induction motor is designed primarily for constant speed, it should be chosen for such work. Where wide variations in speed are required, it will be found that a direct current motor will ensure ready control and a prompt variation of the speed.

In the application of electric drive, two general systems are now in vogue, namely, the operation of each individual machine by a single motor, commonly termed "individual drive," and the operation of machinery in groups by means of line shafting, which in turn is driven by a motor, this plan being generally designated as "group drive."

The relative values of the two methods must be determined in every instance by a careful analysis of the requirements of the installation, and while there are many successful examples of economical group drive, it is now the consensus of competent opinion that in a large majority of cases the highest efficiency, both for the machinery to be driven and for the electrical equipment, can be best obtained by the application of separate motors to each unit. This is especially true where the operation of the machines is intermittent, as in this case the cost of current, if obtained from an outside source, is entailed only during the actual operation of the machine.

If, on the other hand, the plant utilizing motor drive is provided with an isolated generating outfit, the size of the prime mover and generator, as well as the power factor in the case of alternating current plants, will be appreciably affected by the choice of group or individual drive. In the latter case, each machine can be equipped with a motor which will most nearly meet the exact requirements in regard to the maximum desirable speed and the amount of power delivered at the driving shaft.



An interesting example of direct electric drive—a nine-section newsprint machine operated by nine motors, direct connected to each section. The motors are of different sizes and operated at various speeds. One is of 100 h.p. running at 136 r.p.m., while another is 30 h.p., at 98.5 r.p.m. The prime mover is a 500 K.W. turbo generator.

Proper Care of Portable Electric Equipment

Small Tools Do Not Always Receive the Attention They Deserve —Reliable Service When Properly Cared for—Avoid Using Excessive Voltage—Suggestions for Avoiding Trouble

THERE are many points in connection with the use of electric drills and grinders which do not always receive the attention they deserve. The dissatisfaction occasionally expressed can invariably be traced to the lack of protection devices, which are indispensable if efficient service is to be obtained. Abuse in use is another cause of machines being out of service.

When carefully safeguarded and used electric tools will give the same satisfaction and be as reliable as any of the other tools in the machine shop. It is not expected, says the Machinery Tool Review, that every person who uses the machines will be fully posted concerning the electric motor part of the equipment. It therefore devolves upon those in authority to so protect the motor when in use that it is made as fool-proof as possible.

Guard Against Heavy Currents

The most common trouble is in the "burning-out" of the insulation of the armature and field magnet windings. This is caused by excessive currents being allowed to pass through the machine, which are more than the insulation was designed to withstand. The remedy is to fit other devices which will burn out, in the event of short circuit or overload, instead of the motor windings. It is cheaper and quicker to refit a few inches of fuse wire than to pay for the re-winding of the armature or field coils or both. Large electric motors are always well protected. Why not adequately protect the smaller ones, which are more in need of safeguards? The latter will not stand up to heavy overloads like the larger machines.

Claims are sometimes made that small electric tools can be run from any lamp socket. If a machine was so used, it would at times be entirely without protection. When all the lamps on that particular circuit were lighted, the circuit fuses would invariably safeguard an electric tool being used at the same time on that circuit, but when lights are out and the machine only is in use, it is possible to pass through that small motor the full current that the circuit fuse can carry. Small motors, used in this way, have often burned out, leaving the circuit fuse intact.

Protect the Motor

Much trouble and annoyance will be saved by providing a separate fuse and a separate plug and socket at intervals around the shop. The electric tools can then be used from these sources of current supply. It is also advisable to fit a type of wall plug which is equipped with an "earthing" terminal. This will carry away any leakage currents from the motor framing and also safeguard the operator from electric shock.

When machines of different capacities are in use in the same shop, it is advisable to definitely specify that certain machines should be used from certain wall plugs. Otherwise there is a possibility of the smaller machines being connected to a socket which is fitted with a gauge of fuse wire too large for the rated capacity of the smaller machine.

A method of overcoming this difficulty is to fit a different size of wall plug for each size of electric tool in use. The plug on the flexible wire will then only fit its mating socket. This arrangement should not restrict the area over which the machines can be used. They can be fitted with a longer flexible wire if necessary.

Use Drills Carefully

Lack of care when using electric drills is a common cause of machines being sent for repairs. Most of these machines are equipped with series wound motors, and attempts to start up the machine when pressed tightly against the work invariably results in an excessive current flowing through the standing machine.

Another cause of failure occurs when drilling through thin metal, angles, etc., the trouble commencing when the cutting edges of the twist drill break through on the other side. At this time, unless the pressure on the tool is momentarily released to enable the twist drill to clear itself, the cutting edge is liable to become locked, the machine stops with full current on, and the insulation fails.

Small electric motors must be kept clean, and it is advisable to instruct a competent person to take them apart regularly at short intervals. All dust should be cleaned away, new brushes fitted where necessary, and grease placed in the gear box casing. Any small repairs can be effected and the frayed flexible wire bound with insulating tape.

Use Armoured Wire

The fraying of the cotton cover of the flexible wire is a common cause of short circuits. This can be overcome by the use of armoured flexible wire. Something is sure to happen when a laden barrow is wheeled over unprotected wire lying on the floor.

Many of the electric drills can be used upon both a.c. and d.c. supply currents of the correct voltage. When used upon a.c. these are single-phase machines, and there is no difficulty in fitting them to two or three-phase supply. It is only necessary to connect the machine to one phase, as would be done when wiring for lights. When more than one machine is being fitted, they should be spread over the other phases to balance the system.

A word of caution is necessary regarding the very small high speed electric grinders on the market. Some of these grinders run at 10,000 r.p.m., and are listed to mount a 6 in. dia. grinding wheel. It is dangerous to use a 6-in. vitrified wheel at this speed. An elastic wheel of this size would also be running over the recognised safety limit of speed. A 4-in. dia. elastic wheel usually gives every satisfaction.

LARGE CRAWLER CRANE

An interesting development in the construction of cranes has recently been announced by the Link-Belt Co. of Chicago. This new machine, known as a crawler-crane, marks a forward step, from an engineering standpoint, in the art of building cranes of the caterpillar type. A severe preliminary test has demonstrated that this new Link-Belt crawler crane is mechanically perfect. The condition that this machine has been called upon to meet from the first day of its operation, in connection with the building of a new road through a swamp, consisting of unloading itself from the railroad car, traveling over very uneven country to lay down wooden platforms, in order to obtain sufficient bearing area to carry the weight, and starting the work of digging in several feet of water, put the machine through about as severe a test as it will ever be called upon to meet.

The following is a quotation from the report of the crane operator:

"This machine is working in a marsh on floats which weigh about 2½ tons each. The crane lifts them and the clam shell very easily. The material handled is marsh mud and sand. The crane is moving from 300 to 400 yards in 11 hours, with a light ¾ yard bucket. It uses about 25 gallons of gasoline in this time. This yardage does not include a considerable amount of mud overburden, which cannot be used on the road bed and is dumped back in the ditch. The oil added to the crank case is about 1 quart from the time the crane was started working. Water added in radiator was 1 gallon in three days. From the operating point it takes very little effort to handle the levers, and this makes the machine run smoothly and quickly. The hoist drum clutch is the only clutch that has been adjusted since the crane left the shop, June 7th."

Fibre Now Extensively Used in Electrical Work

Improved Methods of Manufacture—Tougher Than Horn, Lighter Than Aluminum and Almost As Hard as Iron—Applicable to a Large Range of Service

THE USE of fibre in the various industries has become quite widespread during the past few years, and in fact, many manufacturers are only now beginning to realize how varied are its uses. As far back as 1859, Thomas Taylor, an inventor and chemist, secured patents on vulcanized fibre, but of course since that time many improvements in the method of manufacture and quality of material have taken place.

The electrical, mechanical and transportation fields have especially benefited through the use of fibre, for many parts previously made of more exp sive material are now either stamped or machined from fibre. Through the courtesy of Mr. Webster, manager of the Diamond State Fibre Co., Carlaw Ave., Toronto, we are able to present some of the fields in which their product "Diamond Fibre" has been successfully used. These will give readers at least a brief idea of the variety of parts which can be made from such material.

First of all, what is fibre? Briefly it is a high grade of vulcanized fibre, a material which is said to be tougher than horn, almost as hard as iron, and yet lighter than aluminum. It does not crack, split or break with ordinary use, and is impervious to oil or grease. Its tensile strength (at least the product made by the above mentioned concern) is 12,000 to 15,000 lbs. per square inch; its resistance to compression is approximately 40,000 lbs. to the square inch, while tis dielectric strength is from 200 to 400 volts per mil of thickness. It is also non-corrosive, and does not deteriorate if subjected to moisture or submerged in water. If desired, it will take a high glossy finish, and can be secured in various colors.

The automotive industry make such parts as battery box linings, brake bands, bushings, conduits for wiring, gaskets, all sorts of insulators, speedometer gears, switch handles, washers, etc., etc., from fibre and the starting, lighting and ignition systems lend themselves admirably to this material.

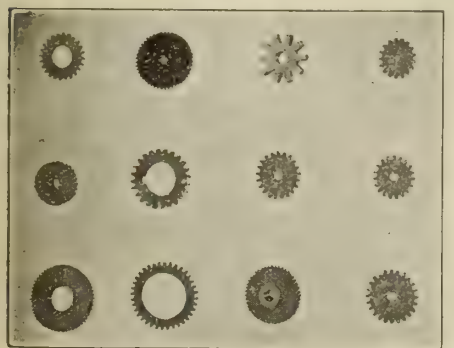


Fig. 1—Showing Some Gears Made from Condensite Celoron.

Electrical Field

In this field there are so many parts made of fibre that we will not even attempt to list them. However, here are a few parts: Bushings, cleats, commutator rings, fuse tubes, lightning arrestors, parts for dynamos and motors, switch bars and handles, etc., etc.

The mechanical field is another very large user of this material. Parts such as bearings, brake shoes, friction straps, gears, gibs, pinions, pulleys, pump valves, etc., are made, and in many cases considerable machining is performed. Then in the sheets, rods and tubes we find all sorts of stampings, bent shapes and so on. Quite a common practice is to make built up gears from steel washers and fibre washers placed one after another, this making a strong, smooth running, and practically noiseless gear.

In the transportation field we see fibre used in making braddock plates, engine box liners, ferrules, fishplates, head pieces, switch shims, etc., etc., and in the textile field such parts as bobbin boxes, bobbin heads, lacing combs, shuttles, spool heads, thrust washers, gears, etc., are made from this material. One of the two illustrations accompanying this article show a few examples of the variety of parts which can be made of fibre.

Another Material

The firm mentioned previously in this article also make another mater al known by the trade name of "Condensite Celeron" which is really hard fibre with the added quality of being waterproof. This feature of course opens up new uses, and as in the case of the regular fibre, this new material is available in sheets, tubes and rods. The product can be best described as vulcanized fibre thoroughly impregnated with Condensite and then hardened by heating. Condensite again is a product made from a combination of phenol and formaldehyde, and when hardened by heating it becomes an extremely water-resisting material, possessing high dielectric and mechanical strength.

Hot water or solvents such as alcohol, acetone, benzine, etc., will not hurt the product we are speaking of, and it is but little affected by hot solutions.

Hot water, or solvents such as alcohol, acetone, benzine, turpentine, etc., will nor hurt the product we are speaking of, and it is but little affected by even strong solutions of nitric, sulphuric, or hydrochloric acids. However, it will carbonize if brought into contact with hot solutions of these acids, and is affected by strong hot caustic solutions.

The new material is used very extensively in the electrical field, and is particularly adaptable to radio work. This is in fact one of its largest uses. Gears made of this material are well able to stand high speed, and will eliminate noise and vibration, according to the makers, and gears made from Condensite-Celeron are already in use on heavy duty equipment such as punch presses, planers, boring mills, lathes, milling machines, gear hobbers, etc.

Suggestions For Machining

In offering suggestions for machining, the makers say: Parts made from this material can be punched, shaved, sheared, turned, sawed, drilled, milled, planed, threaded, engraved, etc., in fact with the exception of the asbestos grade, can be reached in practically any manner possible to machine metal. It cannot be molded, but when in the uncured state, can be formed to special shapes.

It will also take a high polish, and successful machining depends chiefly upon keeping the tools sharp. Tools operate best at high speeds, except where the cut is large enough to heat the tool too much. Work should be turned to size wherever possible with one cut, but where two cuts are found to be desirable, the finishing cut should

Good Lighting Makes for Lower Plant Costs

Reduces Accidents and Spoilage and Increases Individual Production—Promotes Cheerful Surroundings—Poor Distribution of Light Not Only Dangerous But Costly—Lamp and Its Position, and Not the Ornaments That Count—A Satisfying Installation

By J. T. SCOTT

GOOD lighting is profitable. Production is needed and more of it at the minimum cost. For this reason, one of the most important contributing factors at the present time is that of good industrial lighting. Here are four of the more important reasons: 1. Reduced accidents. 2. Reduced spoilage. 3. Increasing individual production. 4. Promotion of more cheerful surroundings.

A short consideration of these reasons will prove helpful.

Accidents caused by insufficient lighting or not enough to see what one is doing. Deep shadows may hide dangerous objects and be deceiving. Glare from unshaded lights may cause momentary blindness and entanglement with moving parts of machinery. This is the result, not of insufficient illumination but of poor light distribution. A sequence of small accidents will quickly cost more than the sum required to secure adequate and proper illumination.

Spoilage.—Articles spoiled simply because a workman "didn't see"—make good production cost just so much more, makes it harder to complete, makes profits smaller.

Production.—Good lighting takes the brake off manufacturing effort. It eliminates delays. Tools are easily found; readings are made more accurately and in less time; it enables the operator to keep on at a more efficient rate of production.

Author is Illuminating Engineer in the Sunbeam Lamp Division, Canadian General Electric Co.

Morale.—The worker feels better under the influence of good lighting. There is less eye fatigue, less headache, and a more comfortable working atmosphere. It is readily agreed that a happier worker is a better producer. Then there is less chance for shirking, and no dirty places to breed carelessness.

Cost of Proper Lighting

Conditions vary so much that it is not possible to lay down a general rule applied to likely cost. It can be said, however, that the increased cost of better lighting totals but a fraction of the payroll cost—probably about one per cent.—and the return in increased production is easily measurable to five or ten per cent. A reference is made later to a point that might also be emphasized here. When getting plans or estimates for lighting, remember that you are buying light not ornamental fittings and equipment. It is the lamp and its position that count—not the ornaments that some contractors seem willing to sell.

What is Good Lighting?

Common sense is the best guide as to what is satisfactory lighting. Foundry work and stock room lighting is of lower intensity than that required for first class machine working.

You can readily find out whether your plant is up to standard by measuring its illumination value with a foot-candle meter. This is a handy little measuring instrument that can be carried around the shops, and it will give direct measurements of light values.

The foot-candle meter also enables you to test the efficiency of your electrical contractor and to get the job done right. In Figure 1 you see the superintendent checking up the shop illumination—seeing is believing.

The Units Used

A short table of the illumination values recommended is set out here. The intensities of lighting are defined by foot-candles.

TABLE OF FOOT CANDLES RECOMMENDED

Stores	5	f.c.
Stairways	3	"
Assembling Med.	8	"
Fine	12	"
Engine Rooms	4	"
Foundry	6	"
Forging and Welding	10	"
Inspecting	15	"
Machine Shop	10	"
Drafting Room	12	"
Office	10	"

The shops engaged in rough work will be well lighted with 4 or 5 foot-candles; if accurate work is being done then 8 to 10 f.c. would be required, or even more foot candles might be desirable. The work on dark objects of course will always require more light than operations on work easier to the eyes.

The unit of light used the foot-candle, might be briefly defined as the amount of light covering an area of one square foot with an intensity of one candle-power. Thus an illumination value of say 10 foot-candles, means an area of one square foot lighted to the equivalent intensity of ten candle-power.

Fig. 2—Well Distributed Lighting in Large Manufacturing Plant

MOUNTING HEIGHT OF UNIT

Above Plane of Work	Above Floor	Permissible Distance Between Outlets	Distance Between Outlets and Walls
4	6½	6	3
6	8½	9	4½
8	70½	12	6
10	12½	15	7½
11	13½	16½	8
12	14½	18	9
13	15½	19½	9½
14	16½	21	10½
15	17½	22½	11
16	18½	24	12
18	20½	27	13½
20	22½	30	15

Table of Spacing and Mounting Height.

Figures are for feet. Plane of work is assumed to be 2½ feet above floor. When work on a plane higher or lower than 2½ feet, then work from first column.

While the word "foot-candle" is used for intensity of illumination on areas, the word "lumen" is used to express light quantity. Thus all mazda lamps are rated as having an output of so many lumens. As a fairly near figure for reckoning, one may take 10 lumens per watt as a working basis. Then knowing the number of square feet to be illuminated, and the intensity of light required in foot-candles, you can choose a lamp having the required number of lumens.

The methods used in calculating the plans for installation of lighting equipment were given very fully in Canadian Machinery during April, 1922, during a course of articles by the writer, dealing with modern illumination.

The requirements of any satisfactory installation are:

1. Sufficient light on all parts of the working area.
2. Moderate light on adjacent areas and on the walls.
3. Freedom from glare and glaring reflections.
4. A system, simple, reliable, easy to maintain and of low operating cost.

With regard to the second point above, it should be remembered that the color of painted surfaces, walls and ceilings are a material factor. It is generally better and more economical to choose light colors wherever possible and thus obtain the benefit of the aid of such colors as white, light grey, buff and stone.

Effect of Cleaning

A large loss of light is allowed by not cleaning regularly all illumination equipment: lamps, shades, reflectors, etc. It is quite easy to lose 40% of the light paid for by a layer of dust and dirt. This is wasteful expenditure and could be saved by the periodical use of soap and water.

The reprint of Table 2 giving spacing and mounting distances will perhaps prove useful as a guide in checking up all installations that are being re-considered. A distribution of equipment that measures fairly close to the distances quoted, will give a very good average illumination provided that the correct size of lamp is used.

Finally, when you are considering any plans for increasing the values of your illumination, buy "lighting," not "lighting equipment." Good lamps of ample light giving capacity, properly spaced and shaded to eliminate glare. That is all there is to it. The cost will be very little and the gain will be considerable in satisfaction and production.

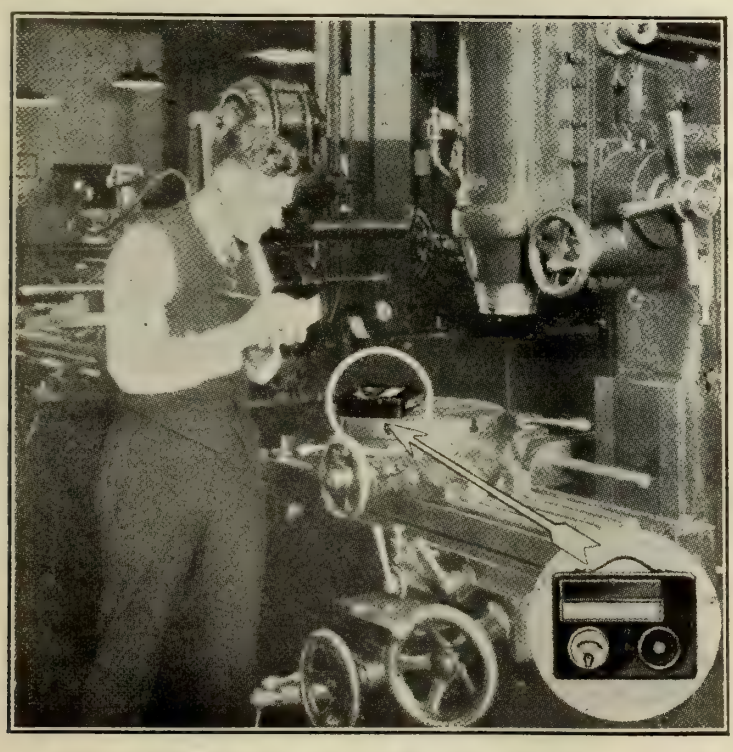

Fig. 1—Checking up Shop Illumination

ELECTRIC FURNACE FOR NON-FERROUS METALS

(Continued from page 19)

This trough of carborundum is packed with granular carbon material, and when the current passes into this material in the trough it brings it to incandescency, and the heat thus generated is radiated down upon the metal on the hearth of the furnace below. The switch may be closed into any one of nine positions, thus giving an easy and accurate method of control over the furnace voltages and hence exactly controlling the temperature within the furnace chamber.

After the switch has been closed and the metal charged into the furnace no further attention is required from the operator until it is time to pour the metal.

This construction entirely eliminates any complicated parts which might get out of order, increases production and forms as simple and accurate a method of melting non-ferrous metals as has so far been developed. These furnaces are built in a range of sizes from 200 pounds up to 2,000 pounds. A multiple of these units gives an extremely flexible arrangement for handling any tonnage or variety of alloys. In the United States there are more than 100 of these furnaces employed in various non-ferrous foundries.

Among the Canadian installations the following plants are typical of the modern foundries which are adopting electricity as a melting medium for their non-ferrous alloys:—

Dominion Steel Products Co., Brantford, uses a 50 K.W. furnace; 500 to 600 pounds hearth capacity; melting rate of 250 to 300 pounds per hour. This furnace is used chiefly for melting red brass and bronze for bushings.

Monarch Metal Company, Ltd., Hamilton, have installed a 75 K.W. furnace with 800 to 1,000 pound hearth capacity and a melting rate of 500 pounds per hour. This furnace is also used for red brass and bronze mixtures running high in lead. This furnace is used chiefly to produce railroad bearings.

Canada Metals Company, Ltd., Toronto, employ a 75 K.W. furnace, producing a wide variety of materials, among which are plumbers' supplies, valves and miscellaneous castings, also yellow and red brass ingot. They are able to melt a wide variety of alloys in the same furnace as with the Baily unit it is possible to change immediately from one alloy to another and it is never necessary to keep molten metal in the furnace as a priming charge.

Union Screen Plate Company, Sherbrooke, Que., use a 75 K.W. furnace for producing heavy castings. Their alloys are chiefly red brass run into screen plate casting molds.

Adapting a Portable Tool to a Variety of Uses

Makes Ideal Equipment for Garage and Service Station—Working Range Increased by Means of Attachments—Cradle of Stand Can Be Adjusted to Any Angle—Simple Construction

STARTING with the idea that the Hole Shooter, an electric portable drill, could be adapted to many other uses in addition to the drilling of holes, the A. H. Peterson Manufacturing Co. of Milwaukee, has developed a number of unusual attachments which make this tool a whole machine shop of usefulness. Practically all these devices have been designed particularly to meet various requirements of the garage and service station, and industrial plants. With these attachments, there are so many practical uses for an electric tool of this description, that it becomes infinitely more productive than a mere electric drill could ever be. Many garages have found it possible to do work with the Hole Shooter and its combinations, which heretofore required separate units of equipment costing many times the price of this unique combination.

Among these developments is a radial portable drill press stand, as illustrated here, remarkable for its simplicity. Other inventions include a battery terminal opener; end bristle wire brushes, of various grades and sizes which are mighty useful in removing carbon from cylinder heads, burnishing work, removing paint and varnish, etc.; a commutator saw-wheel on a flexible shaft; rotary taper files; special emery grinding wheels; special buffers, which are used to excellent advantage in simonizing bodies as well as for ordinary buffing work, and many other attachments.

The drill press stand is designed to hold the portable electric drill rigidly at any angle vertically or horizontally. When adjusted for use in a perpendicular position, the combination serves as a portable drill press. With the appliance adjusted in a horizontal position, the combination serves as an electric grinder, buffer or polisher. The spindle speed of the Hole Shooter is high enough to make this thoroughly practical. Machines of larger capacity will not do work of this sort because of their necessarily slower spindle speed. Several garages and shops have been able to eliminate the purchase of two distinct and expensive units by adapting this combination to their varied classes of work. The saving in most instances has been over 60 per cent. in initial cost. Operating cost is also reduced, so this equipment is a mighty profitable investment. The complete drill press stand weighs only 30 lbs. With the electric drill included, the total weight is only 34 lbs. Thus the whole outfit is easily portable.

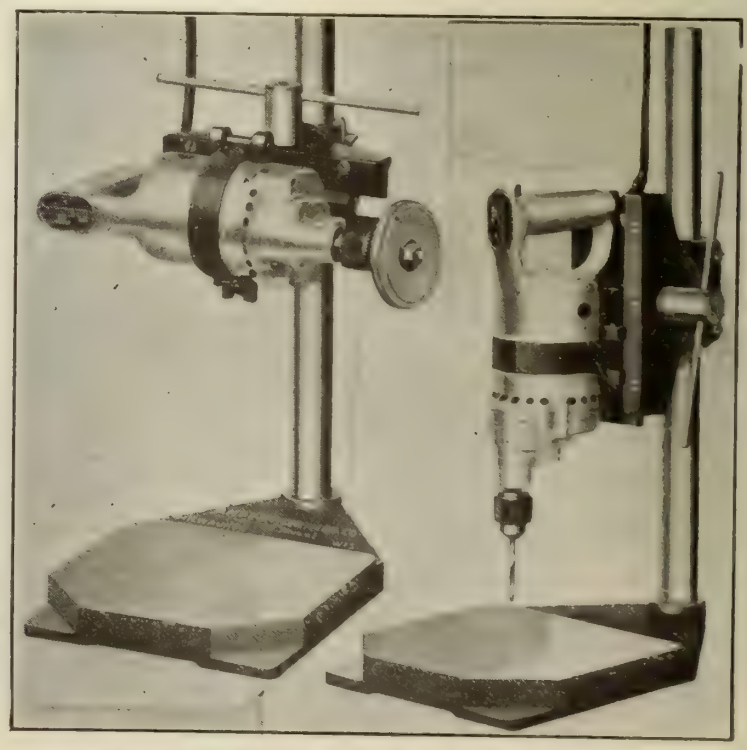
Simplicity of Design

The simplicity of its construction brings the cost low and eliminates possibilities of the outfit getting out of order. Sensitive and accurate control of the drill press rack is obtained without resorting to expensive and cumbersome counterweights, chains or spiral springs which are embodied in other small drill press stands. The fact that the cradle of this stand can be adjusted at any angle vertically or horizontally is also a unique and very practical feature.

The battery terminal opener is a simple, effective lead cutting drill bit, developed after extensive experiments. It cuts a hole 13/16 inch in diameter. The shank of this drill is turned down to fit the ¼ inch Jacobs chuck of the Hole Shooter.

The end bristle wire brushes are particularly desirable in various classes of garage work. The stiffer brushes are practical for cleaning carbon from cylinder heads. They are made in two sizes, suitable for getting into cylinders of large and small diameter. Other brushes are suited to removing rust and hard encrusted dirt from springs, wheels and under-castings of cars, burnishing metal parts before refinishing, removing paint and varnish, cleaning rough castings, polishing and sanding wood surfaces, etc.

The machine itself, used with regular drill points, is a valuable necessity in garages, service stations, machine shops, maintenance departments, etc. Its drilling capacity is up to ¼ inch in metal and up to 5/16 inch in wood. The new Hole Shooter has a motor that cannot be stalled on any work within its rated capacity—a motor that is a real achievement in the drill industry. Drilling oil holes, holes for fenders, snubbers, installing instruments on dash or cowl, making special wiring holes and many other uses are within the range of adaptability of this four-pound portable electric drill. These uses, together with those mentioned above make this tool a "whole machine shop of usefulness."



Showing the Adaptability of the Portable Electric Drill.

A STEEL FOUNDRY IN A GARDEN CITY

Almost the last place in which one would expect to find a steel foundry is one of those garden cities which enlightened town planners have constructed as a model. Nevertheless, in a garden city near London, Eng., there exists a steel foundry which is so well equipped and so well designed that it does not interfere in any way with the high standard of general well-being appropriate to a garden city. Normally this foundry employs about one thousand workers and its equipment includes a large electric furnace. The output of the foundry is about eight hundred tons of steel castings per month, and among its specialities is the casting of ships' davits which form an extremely difficult job. In spite of its remoteness from the large centres of raw materials this model steel foundry is very successful in competition with foundries in the orthodox steel districts.

Economies of Electricity in Foundry Practice

Magnetic Hoists Give Valuable Service in Handling Metals—Separators Help Eliminate Waste and Remove Particles of Iron and Steel From Brass Turnings—Charging the Cupola By Means of Magnet—Advantages in Many Industrial Operations

By F. H. BELL

ELECTRICITY and its adaptability to the various requirements of the foundry covers so large a field with such a variety of features that it could hardly be referred to as our subject, but rather as combination of subjects. Since its every day uses have been so thoroughly dissected and diagnosed as to be well known topics, I will omit mentioning the electric light, the electric crane, the electric melting furnace, the electric motor for driving the various machines which are used in and about the foundry, electric welding, signaling, etc., and will devote my attention to one branch of the science, that of the electro magnet.

The electro magnet, like everything electrical and everything magnetic, has the appearance of a phenomenon. We know some of the things it will do, because we have seen it do them but beyond this we know very little. We know, or at least we think we know, that magnetism is a product of electricity, while some electricians of note will argue that electricity is a product of magnetism. Howbeit, they work together.

The word "magnet" was, presumably, derived from Magnesia, a section of Thessaly, on account of a metal which was discovered there which looked like silver and was known as Magnesian stone. This stone had the characteristic of attracting other pieces of the same material as well as being attracted to the North pole. This led to the conclusion that stone of a similar nature was located in the extreme north. This was known as the Polar magnet. Later on a black stone was discovered which had the same characteristics only much more pronounced, this was known as lodestone.

For many years these minerals were used in making compasses and other instruments which required to be magnetized. This, of course, was before these stones or minerals were known as ores. These stones, or ores as we now call them, still exist, and still have these drawing characteristics. When refined and the metallic elements taken from the ore, the ore is known as magnesium while the other is magnetic iron. Magnets are now made artificially and known as electro magnets while the lodestone is known as natural magnet. While modern science has demonstrated that electricity will produce artificial magnetism, certain it is that natural magnetism was known long before electricity was discovered, but not necessarily before electricity existed. Both were probably in existence ever since the creation of the earth but it took time to discover them. Since both had to be discovered—not invented—and neither is understood, beyond knowing what can be done with them it is quite possible that electricity could not exist without the aid of magnetism and that magnetism could not be possible without the aid of electricity. While the name "magnet" owes its origin to the metal magnesium, this metal is not a very powerful magnet. The iron group which includes nickel and cobalt, are the most suited for magnets.

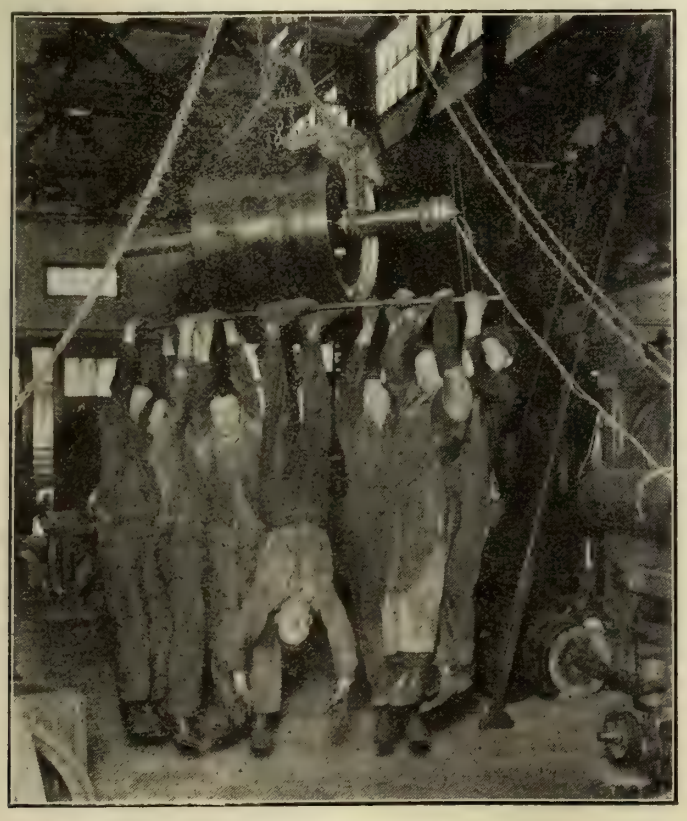
Queer characteristics of the phenomenon are that silver and copper which are the best conductors of electricity will positively repel the magnet. Steel, when magnetized, becomes a permanent magnet, while cast iron has an inclination that way but soft wrought iron which is equally as good a magnet while the current is on cease to be a magnet as soon as the current is off. This is what is known as a temporary magnet.

Were it not for this temporary feature the usefulness of the electro-magnet would be greatly reduced as it would be difficult to disconnect the magnet at will.

In his experiments with electricity Professor Orsted of Copenhagen discovered that if a current passed at right angles to an iron wire the wire would be magnetized so long as the current passed. This effect was easily multiplied by coiling the wire conveying the current round the iron rod or wire in the form of a helix, thus producing magnetism enormously more powerful than could be contained in any permanent magnet. Still later it was discovered that the wire helix alone possessed nearly all the properties of the magnet.

At a subsequent period, Faraday discovered the converse relative phenomena, that the production, or cessation, or any variation in the intensity of magnetism caused the production of an electric current, the developments of which are comprised in the subject of magneto electricity, which proves the contention that electricity may be the product of magnetism, while magnetism may be the product of electricity, and encourages the conclusion that it would be impossible to have either without the other.

The fact that the temporary magnet can be operated instantaneously makes it particularly useful in the foundry, while the fact that its strength can be increased to practically any desired volume makes it useful in lifting enormous weights of metal. As a demon-



Bar in contact with magnetic pulley supporting six men; one man suspended by nails in shoes

stration of what can be done with magnetism we will illustrate a little stunt which was performed at the works of the Dings Magnetic Separator Co., Milwaukee, Wis. A pulley from one of their standard separators was suspended from the ceiling of the shop on a short piece of rope. A wire was connected, carrying the current with which to magnetize the pulley. Against the bottom of this magnetized pulley an iron bar was placed. This bar being flat and the pulley being curved, there could be but a very small surface contact, yet that bar was held against the pulley with a tenacity sufficient to hold up the six men who are seen to be hanging from it, while the seventh one, who is hanging with his head down, is held suspended by the pegs in his shoes.

Knowing the convenience as well as the power of the electro magnet we will look into a few of its uses, and since we have the illustration of the separator drum we will begin with this.

Magnetic separators have two separate and distinct duties to perform in the foundry. One is to remove particles of iron and steel from brass turnings so as to leave the brass pure, while the other is to redeem good iron from waste refuse.

Eliminating Dangerous Nodules

That iron is a dangerous impurity in brass and copper alloys is a well established fact. Many attempts have been made to produce a good inexpensive bronze by combining iron with copper and its alloys, but all such experiments have resulted in proving that unless the carbon content of the iron is removed the results will be unsatisfactory, and since all iron contains carbon there is only one real solution and that is to keep the iron out. When iron or steel finds its way into the crucible with brass chips, it does not alloy but produces a dangerous mechanical mixture. The iron forms into small nodules and these nodules seem to absorb all the carbon in the surrounding metal, forming themselves into steel harder than the hardest chilled tool steel. These nodules vary in size from a small pin head to a pea, according to how much the metal has been stirred while in molten condition.

As far as the foundryman is concerned the castings would seem to be all right but it is from the machine shop standpoint that the trouble is expected. In machine brass castings, the edge of any steel tool will break when it strikes one of these nodules. This is one of the reasons why the presence of iron in brass castings is dangerous. Thousands of dollars worth of tools have been ruined, much valuable time lost and a great deal of annoyance has been caused by these troublesome nodules. They are especially dangerous to tools in automatic machines because the operator does not know for a considerable time that a tool has been damaged, and during this time a lot of good work may be spoiled.

In rolling brass containing these nodules into thin sheets the surfaces of chilled rolls are sometimes dented. In polished work, wherever these nodules do not come in contact with any tool but are close to the surface, rusty spots will appear upon the brass.

It has been fully demonstrated that with the utmost precaution, it is impossible to keep brass chips free from iron and steel. In shops where both brass and iron are machined, the brass chips always contain iron. No matter how carefully the lathes and machine tools are cleaned between operations on different metals, iron dust and small chips left in the crevices of the machine will contaminate the brass chips. Even in places where brass is worked exclusively, more or less iron and steel finds its way into the brass chips. Even the wear from the steel tool will do some mischief, and then there are washers and nuts and various other iron articles which manage to get in unobserved. If anyone of these happens to get into the melted metal, bad castings are to be expected. Flues of different kinds have been tried out but so far there is only one remedy and that is to either use a flux which will remove the carbon, or else eliminate the iron entirely, and the last mentioned is the one which is the real cure. All are agreed that it is not safe to melt brass or copper chips without first treating them with a reliable magnetic separator, and the question arises, "which is the best?" There is the permanent steel horse-shoe magnet which is still sometimes used, but the separator having the magnet energised by electric coils is much more efficient than this as it does not require brushes to scrape the chips off the drum but has all the advantages and conveniences which we have seen accompany the temporary soft iron magnet.

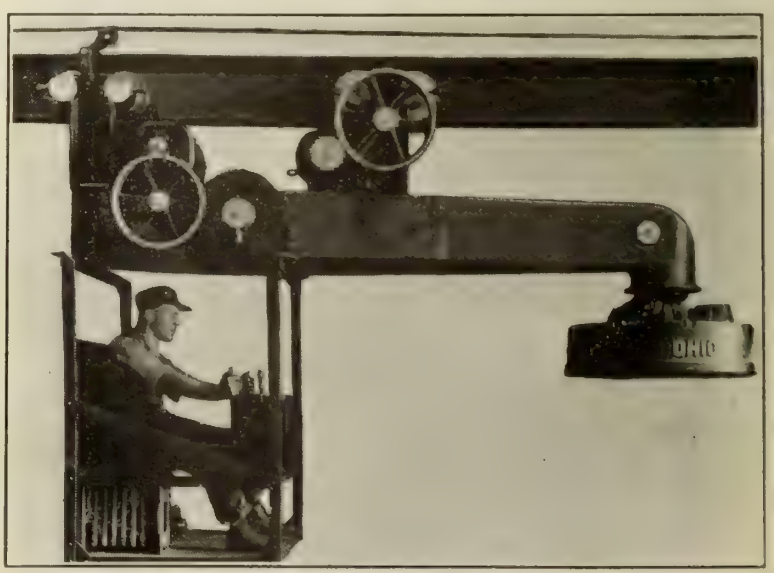
Reclaiming Good Metal

Magnetic separators are used in iron foundries for reclaiming good iron which would otherwise go to waste. Cinder mills will separate the iron from the cinder, but much of the finer particles of iron will pass through with the ground cinders and will be wasted. If this is passed through the magnetic separator it is surprising how much iron will be recovered. In some of the best foundries the molders' sand heaps are passed through magnetic separators to remove gaggers and scrap iron which would otherwise have to be picked out by hand and this not very effectively. This can be accomplished best by having a screen attachment so that the sand is first sifted out without going over the magnet, while the siftings go through and the magnet separates the iron from bits of brick or other undesirable material which is invariably in evidence.

Lifting Magnets

Lifting magnets are becoming quite common of late but are perhaps not as well known as they should be. Illustrations of these magnets are to be seen in most every technical paper but are passed over as though intended for some one else, but if properly understood they would be more popular. They are in no way connected with the mechanical work of the lifting machine, but simply take the place of hooks, chains, buckets, etc., for fastening the load to the crane or derrick. For instance in ordinary practice if pig iron is to be hoisted up to the charging floor it is usually placed on a barrow which is in turn wheeled to the elevator and raised to the proper level, where it is wheeled off and dumped in a heap, only to be rehandled and charged into the cupola.

With the magnet it can be attached to any kind of a crane in place of the hook and dropped down on top of a pile of pig iron. The pig iron will adhere to it when it is lifted away. When delivered to the proper place on the scaffold the current is turned off and the pig iron drops on the heap. In lifting scrap iron all the smallest pieces will be picked up and saved. Lifting pig and scrap iron are among the simplest op-



Roots Cupola Charging Hoist

erations. Where the magnet is most useful is in handling pieces which would require a lot of chains and hooks to secure them to the crane. The magnet only requires to touch the article and the crane can begin hoisting. These magnets may be attached to portable cranes or any other lifting machine and they will do the work.

One of the most useful occupations to which a magnet may be put is in connection with the cupola. This machine is operated by electric motors with the exception of the actual gripping of the metal which is done by a magnet. It is the latest thing in charging the cupola and has just recently been developed by the P. H. and F. M. Roots Co. of Connersville, Ind. It has all the conveniences of an electric crane and was designed to reduce fatiguing manual labor, with its accompanying cost. In addition it saves much in maintenance of cupola linings. It consists of a cantilever charging arm, with double swiveling four-wheel trucks. All four wheels of one truck are driven, while the trailing truck has an up-thrust roller to compensate for any cantilever action which may occur from overloading. This hoist covers more features than any hoist heretofore developed. The cantilever arm is run out to the yard, where the magnet is lowered down onto the pile or iron, which as we have already shown, adheres to the magnet and is raised to the charging floor level but instead of being deposited on the floor is charged right into the cupola by means of this cantilever arm which projects beyond the limits of the I beam on which the charger travels. Iron charged in this manner can be depended on to be properly placed, because by locating the magnet centrally in the cupola the iron is dropped to a position concentric with the centre line of the cupola, avoiding all contact with the brick lining, and in a position to melt more evenly. This is impossible where charges of materials are fed by hand, dumped from cars, or charged by chutes through charging doors of cupola. For lifting fuel and the fluxes, an automatic hook with drop bottom bucket is used in conjunction with the magnet.

ELECTRICAL INDUSTRY USES MANY FIBRE PARTS

(Continued from page 23)

remove at least ⅛ inch. If a lighter cut is taken it is not always possible to secure a uniform diameter. The turning tool should be ground to a diamond point and rounded off slightly and given plenty of clearance and rake.

As stated previously, this material lends itself particularly to the radio and electrical fields, and radio panels are very often made from this substance. To go into all the parts made from fibre and this latter mentioned product would take a volume in itself, but sufficient has been said to interest the reader and show the possibilities. Within a short time we can be sure of still further developments, for new uses are being discovered almost every day.

UNIVERSITY COURSES

The announcement made here last week that courses for export managers are to be held at Toronto and McGill Universities early next year should be of more than passing interest to every Canadian manufacturer. Every manufacturer catering to foreign markets employs an export manager who is in charge of this branch of the firm's output. The Federal Department of Trade and Commerce, recognizing this fact, and being desirous of assisting manufacturers to promote the export trade of the Dominion and to put same on a thoroughly sound basis, devised a scheme, in conjunction with the Commercial Intelligence branch of the department, to aid the manufacturers by equipping them with knowledge that will enable them to meet competitors in foreign markets on the best possible terms. The principal part of this scheme will be the courses.

The department, holding the opinion that the average export manager of Canadian manufacturing firms was not as well acquainted with the requirements of the foreign markets as he might be, concluded that no better method could be devised to correct this defect than by a course of instruction that, if taken, could not but help these export managers in the conduct of their trade to better comply with the demands of the foreign markets to which they were catering. Accordingly, Toronto and Montreal being the principal exporting circles, the Toronto and McGill Universities were approached and, these institutions having expressed their willingness to co-operate, it was decided to offer a course at each of these seats of learning. The courses will extend for two weeks, opening at Toronto on January 15 and at McGill on January 29. They will consist of lectures and demonstrations during the day and, possibly, a night course for local manufacturers, with a view to a thorough study of foreign markets, their requirements, and problems to be met and overcome.

No definite program has, as yet, been arranged, nor is one likely to be until late in the fall, but, as a basis from which to work, the Department has suggested the following ten subjects to be dealt with:—

1. Commercial geography; 2. problems of marketing; 3. transportation; 4. foreign tariffs; 5. Canadian Government services and, particularly, the functions of the Commercial Intelligence Service; 6. documentation; 7. financing foreign shipments and exchange; 8. correspondence; 9. marketing and packing, with practical demonstrations of the best methods of packing and experiments in testing the strength of packing; 10. general remarks on such subjects as the advantages of courtesy, address, etc.

It should be distinctly understood that these proposed subjects are purely tentative suggestions, the list may be much augmented or, when finally revised and adopted, some may be divided into subsubjects, while it is within the bounds of possibility that there may be eliminations. As at present proposed the lecturers and demonstrators will be drawn from the department, from the trade and from the universities.

Canadian Machinery has made arrangements that it will be in a position to announce the full definite program of the courses as soon as such is decided upon and available, which will probably be toward the end of November.

NEW BELTING SPECIFICATIONS

It will be of interest to Canadian manufacturers to know that the bureau of Standards, Washington, in co-operation with the U. S. Leather Belting Exchange have agreed upon specifications for leather belting in order to guarantee standards of quality on which competition can be fairly based. The belting manufacturers in the United States defined the elements of such quality with an assurance to industrial purchasers that they are receiving leather belting of a quality suitable for their work.

Dealing with the constitution of belting, the specifications require that, as to length, no sectional strip shall be more than 54 in. in length including the lap. The minimum length of any strip shall be 36 in. including the lap, excepting that in double belts one-eighth of the total number of pieces may be between 20 in. and 36 in., provided that these short pieces shall not occur consecutively. The minimum length shall not apply to the end pieces of rolls or cut length. In single belting the strips shall be joined shoulder end to shoulder end and butt end to butt end. In double belting the pieces shall be joined, backbone centre strips shall be used. The backbone mark shall appear running lengthwise approximately in the center of each strip. In all double belts from 8 in. up to 10 in. in width, backbone center strips shall be used in one ply and the backbone mark shall appear running lengthwise approximately in the centre of each strip. The other ply shall be cut from the location prescribed first quality stock. In all double belts 10 in. and over in width, both plies shall be made from backbone center strips and the backbone mark shall appear running lengthwise approximately in the center of each strip. The same quality of leather shall be used in both plies of all double belting.

Specifications further require that all leather shall have a minimum tensile strength of 3,000 lbs. per sq. in. of cross section and an average tensile strength for single belts of 3,750 lbs. per sq. in. and for double belts of 3,500 lbs. per sq. in. The average shall be determined from five test specimens selected at random from different parts of the sample being examined. Test specimens shall be cut with a metal die. The edges of the test specimen shall be cut perpendicularly. The minimum thickness inside the gage marks shall be used in determining the specimen.

Portable Outfit Widens Field of Electric Welding

Special Generators Required—Apparatus Fitted to Chassis Mounted on Large Pneumatic Tired Wheels—Reinforcing Seams on 30 Foot Tank—Welding of a Varied Character

By J. A. DUCHESNEAU

PORTABLE apparatus, which is used to generate electric current suitable for welding purposes, has widened the field of application of this particular branch of engineering. It is desirable to have voltages varying between 20 and 50, and, as all standard voltages are 110 volts or higher, it is easily understood that special generators and conductors used in connection with electric welding, must be able to take care of heavy amperages. Operators of electric welding outfits feel that the electrical apparatus is simpler to use than other types. After starting the generator there is only one major adjustment to take the attention of the operator, namely, the rheostat, the operation of which is simplicity itself. The field of electric welding overlaps, somewhat, the field of oxyacetylene welding, but then again, there are many repair jobs and manufacturing operations, that are more easily, and more economically, done with the electric apparatus.

Fig. 1 shows an electric welding generator, of the portable type, driven by a gasoline engine. The whole machine is mounted on a heavy steel frame, which maintains the alignment of the machine. This frame is mounted on the chassis shown. The apparatus is fully self-contained. It can be moved by hand around the shop and is towed behind a truck when it is necessary to do work at a distance from the shop. The apparatus can be entirely enclosed for such trips, preventing its exposure to the weather. The gasoline tank is below the engine crank case, and the fuel is fed to the carburetor through a Stewart vacuum feed apparatus. A governor is fitted to the engine, which keeps the speed, and therefore the generator voltage, constant. To the left, the panel board is seen. Here are located the electrical instruments, switches, rheostat, etc. This firm has several portable machines. This apparatus, is, in a general way, mounted on a similar chassis and has a housing which permits of entirely closing in the apparatus when traveling There are two or three standard a. c. motors kept for the machine so when it is necessary to do a job where only 550 volt current is available the corresponding motor can be placed on the apparatus. A 220 and 440 volt motor is also kept. As will be realized, this apparatus is used when it is required to do a job where there is electricity available. A direct current motor is also kept by the firm. Motors can be changed in 15 minutes. A fan will be noted between the motor and the generator. This fan was placed on the shaft as a safeguard for the generator, which at times showed a slight inclination to overheat.

This machine has been used on emergency jobs where no current was available, with the generator driven by a belt. The motor was removed and the pulley placed on the shaft extension. In using any of these portable apparatus it is a good precaution to ground the frame as it is well insulated from the ground on account of the rubber tires and static electricity is often present.

A large number of jobs in electric welding are done on boilers. There are limitations placed upon the application of this method of repairing boilers, and all major repair jobs must have the approval of the boiler inspector in whose territory the boiler to be repaired, is located.

Repairing Boiler Cracks

Probably the most common repair is a crack. This crack is chipped out as shown at B in Fig. 3. Then the "V" shaped groove is filled in, with the welding apparatus. The welding rod used, is, usually, specially manufactured soft steel. This firm use ⅛ in. and 5/32 in. diameters in most cases of small repairs. After the crack has been filled in as shown at C. a "rougher" is shown at Fig. 4, and is what might be called a caulking tool, and is used with hand or air hammers and close up any pin holes that might possibly exist. The tool is used any time after the weld is completed, either before or after the metal has cooled. In all welds the operator must be careful to build up at one time only that length of weld that he can keep hot, so that the built-up metal will not become unduly hard.

This firm undertook a very interesting job at the shops of the Dominion Bridge Co. A number of large tanks had been constructed for the Imperial

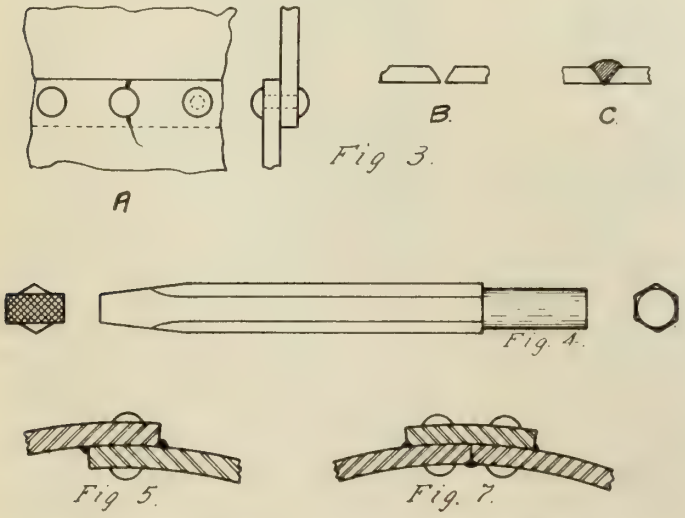


Fig. 3—Repairing Crack in Plate. Fig. 4—Caulking Tool. Fig. 5—Welding a Lap Joint. Fig. 7—Reinforcing Butt Joint.

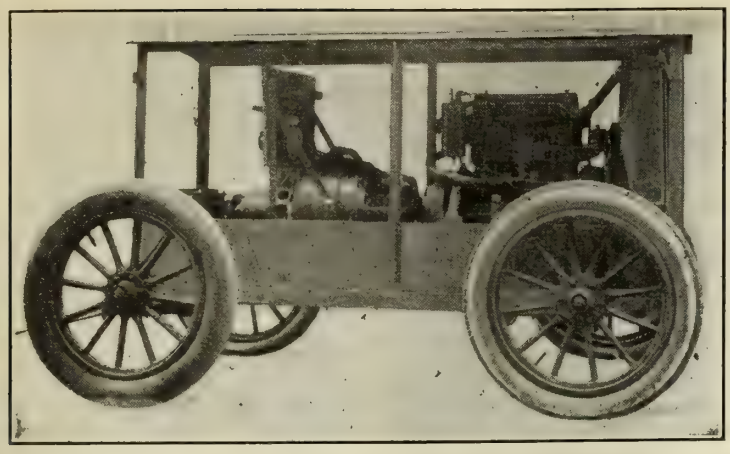
Operator at Work on Bronze Runner



Portable Electric Welding Generator

Oil Co. These tanks were thirty feet long and ten feet in diameter, constructed from ⅞ in. plates. The joints had been lap-rivetted, and, as it was necessary for them to be tested at 200 lbs. cold water pressure, it was decided to weld the joints. This was done as shown at Fig. 5. The job was successfully accomplished.

A job that was somewhat unusual was undertaken at the power plant of one of the large aluminum companies at Shawinigan Falls. One of the bronze runners of a water turbine had become damaged through the breaking of the rack at the head gates. The cracks in the bronze were all welded and there were several pieces broken out that were "built in." Fig. 6 shows the operator at work on this job. Steel welding rod was used and a perfect job was apparently made. The turbine has been in operation since March last and has given entire satisfaction. Another job of interest that was done at Shawinigan Falls for the Shawinigan Engineering Co., Ltd., was the welding of the large new penstock 24 feet in diameter. The joints were butt rivetted and were welded as shown in Fig 7.

This firm has successfully accomplished many electric welding jobs in cast iron. Electric welding in this material has not reached the stages of perfection that it has in steel. This fact is due largely to the varying analyses of cast iron met with and that it is practically impossible to get a welding rod of that material that is entirely satisfactory over the wide varieties of iron met with.

The jobs undertaken are building up broken gear teeth, welding pulley arms, etc. Research and experiments are being continually carried on, and practical experience is growing wider every day. Thus, it is only reasonable to suppose, that in the course of a few years the field of application of electric welding will be very greatly widened.

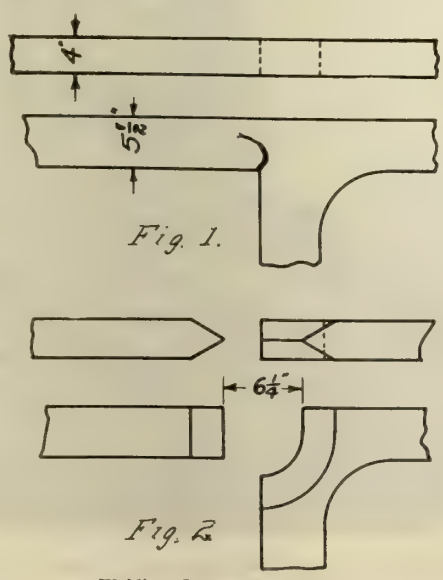
Electricity in Grand Trunk Pt. St. Charles Shop

IN A RAILWAY shop there are often many interesting special jobs that are undertaken and successfully executed, the details of which are only seen by those in charge of the work. It is further regrettable that there are rarely any photographic or other records kept of this class of machine shop work, which later could be worked up into shape for publication. It is not often the good fortune of Canadian Machinery's representatives to be present when some of these particularly interesting operations are being carried on.

A few days ago a very interesting electric weld was noted; in the case of a cracked locomotive frame. This locomotive was brought into the shops and partially dismantled. The crack in the frame is shown in Fig. I. The frame was cut away as shown in Fig. 2. The edges were bevelled at approximately thirty degrees and a piece of steel was machined to fit in the frame. There was no preheating required and only an allowance of 1/64 of an inch for contraction. The electric apparatus was used to amalgamate the inserted piece with the frame and thus one integral piece was made. The weld was entirely successful.

From time to time similar repair jobs are executed. Some months ago a spoke in one of the steel driving wheels of a yard locomotive was found cracked. Owing to the heavy section of the circular rim, no allowance for concentration could be provided. The weld was successfully accomplished by chipping a small "V" around the spoke following the course of the crack. A collar was built up around the spoke which proved to be a successful weld.

There are a large number of small shafts, pins, rods, etc., that enter into the construction of a locomotive. Some of the rods are forged to special shape and are fairly expensive to produce, and at the same time the wear occurs at only one or two points, where it operates in a bearing or guide. These parts are all inspected, upon the tearing down of a locomotive, and if worn, are sent over to the electric welding department. Here are located several operators' "stalls." When the welders are not working on the floor or in the yard, the welding foreman keeps them busy repairing these small parts. In the cases of the pieces mentioned above, these journal sections are built up, about one quarter inch being added to the diameter of those machined sections that are worn undersize. These pieces are then later machined to size and placed in commission once more. No preheating is used in these instances.



Welding Locomotive Frame

There are cases also of forgings that have holes in them that are worn "out of round" or "large." These holes are filled with a plug approximately the size and shape of the hole, and then the welding outfit is used to entirely close up the hole. The pieces are next smoothed up in a miller, shaper, lathe, or planer and the holes re-bored, or re-drilled, as the case may necessitate. In these instances again it is not necessary to preheat the work.

Patches are welded in boiler shells, fire-boxes, tender tanks, and in fact all plate work. There are a number of kinds of repair work where the electric welding process is more desirable than other methods. Preheating is not generally necessary as the net shrinkage or contraction is small, owing to the fact that only a very small section of the metal is heated at one time and contraction is taking place as the welding proceeds. The Board of Railway Commissioners have some rather strict regulations and will not permit the welding of car axles, the running gear of a locomotive, such as side rods, connecting-rods, etc., etc.

The electric welding of cast iron has not been attempted to any great extent in Montreal. Those close to the profession, state that there is not available locally the proper kind of flux or welding rod.

The cost of electric current used in operating a welding apparatus is low.

Points to Watch in Operating the Shaper

Care Should Be Taken to Have Ram Move Freely But Without Vibration—Undue Wear if Oiling is Neglected—Avoid Springing Work When Clamping in Position

THE thousand and one jobs that require to be surfaced on small areas demand the attention of a shaping machine, and next to the lathe it might be said to be the most desirable tool for the jobbing or repair shop. In the larger factories the range of equipment permits of better selection for the accomplishment of different classes of work, but when a shop must restrict itself to a few tools, the shaper will always meet with approval for the class of work generally handled in a limited way.

The character of the work that a shaper is called upon to perform demands the maximum amount of rigidity in construction, and yet with free movement of the reciprocating ram. This is obvious from the nature of the cut and the action of the ram when working on long pieces, or when the cut is made on work at the extreme forward position. For this reason it is necessary that careful attention be given to the lubrication of the forward end, as the overhang on long travel causes the ram to sag due to its weight and causes excessive downward pressure on the lower bearing surface. On the other hand, the action of the cut causes an upward thrust to the front end of ram that presses against the top gib. These two opposing factors will in time, if proper oiling is neglected, cause undue wear on the slide.

The writer remembers operating a shaper some time ago that was affected in this particular way. When the tool was entering the work it would lift up nearly a sixty-fourth before taking the cut. On very short pieces this fault could be overcome by adjusting the gib but this would not work on the longer cuts owing to the uneven wear on the ram and the frame slide, as it would be free in the back position but would jam when moved forward about eight inches. This state of affairs continued until we had a set of fine thread rolling dies to cut. Several attempts were made to complete this job but the result would always be the same—the threads breaking in places on the final cuts. Before this thread cutting job was finished it was necessary to put a day in on scraping and fitting the ram slide.

Keep Tool Rigid

In the operation of shapers, the principles governing the cutting of metals are similar to all other tools. Second only to the proper grinding of the tool is the need of rigidity to the tool support. The cutting point should not extend any lower than is necessary as the vibration and tendency to "dig in" is aggravated by the increased length. If it is imperative that a long tool be used the cutting point should be in a vertical line with the heel of the tool so that excessive resistance will cause the point to take a path away from the surface of the work. In this connection it might also be stated that the vertical side of the shaper head surface should be a snug fit and the back-lash entirely eliminated. If there is any play in the nut or end movement of the screw the possibility of spoiled work by the tool "digging in" is very great. When making vertical cuts care should be taken to have the clapper box tilted over to permit the tool to clear the return stroke of the ram.

In order for any machine to do its best work it is necessary that the oiling of friction surfaces be carefully and systematically done. Lubrication to a machine is like food to a workman—both must be of the proper kind and suited to the particular needs. It should be neither a feast nor a famine. Too much oil may be as harmful as not enough. In many cases a heavy flow of oil is desirable but seldom in connection with machine tools. Where wells are provided to lubricate parts such as gears and worms, subjected to constant thrust, they should be adequately protected from dust and dirt. Oil running down the outside of a bearing or the frame of a machine is only so much waste. Feed and elevating screws on shapers should be kept clean and oiled sparingly, but frequently. The reason for this is to prevent the accumulation of dust on the thread which is drawn into the nut and causing wear, thus shortening the life of the screw.

Supporting the Work

Holding the work on a shaper is a very important point in connection with accuracy of finished product. Whether the piece is held in a vise, jig or clamped to the table, it must be secured in such a manner that all possibility of spring will be eliminated. When clamps are used care should be taken to see that a firm bearing is provided immediately beneath the clamp. Never attempt to use a clamp over a hollow portion. When using the vise see that the work is resting firmly on the parallel supports. After the vise jam is tightened a light blow should be sufficient to seat the work. If it does

Electric Furnaces for Many Industrial Purposes

Great Flexibility Indicated—Efficient and Economical—Makes for Better Working Conditions in Baking, Hardening, Enameling, Heat-Treating, Annealing, Melting and Forging—Application in Soldering, Heating Auto Rims, and Drying Lumber

GREAT is the variety of industrial utilities to which electricity is being applied. This has interesting illustration in the development of heat-treating furnaces for many different purposes. The scope of this field demonstrates the flexibility of electricity, and results actually obtained establish its merit as being economical in every department. It eliminates laborious operations and hence serves to reduce cost; it has been the means of saving valuable floor space by confining certain operations to smaller areas; in the matter of cleanliness, where such is an absolute necessity, it is beyond comparison with gas or oil; there are no offensive odors or excessive outside heat, and its efficiency has been established as beyond question. When it has been given a fair trial and wherever engineering skill has had an opportunity to adapt it to local conditions or particular purposes, results have been satisfactory, and electricity has won favor as a desirable heat-treating medium. Safety insulations and switches have been developed and designed whereby danger from high voltages has been reduced to a minimum and at the same time recording and indicating apparatus constructed whereby the power may be adjusted to the operation, automatic or otherwise, with absolute precision.

Scope of Heating Operations

The statement is made by an experienced electric-furnace engineer that electricity can be used for any heating operation requiring temperatures from 100 to 2,600 degrees Fahr., and for metal melting from 100 to 4,000 degrees Fahr. successfully and efficiently. Here are a few of the applications in Canada of the electric furnace to purposes that may be considered more or less exceptional:—

Baking 10,000 headache tablets per hour.

Baking corn flakes at the rate of 500 lbs. per hour.

Heating 120 auto rims per hour for shrinking on felloes, and also for drying truck bodies.

Electric lead pot, 12 ft. long by 2 ft. wide, heating 30 No. 10 iron wires to 1,550 degrees Fahr. traveling at the rate of 100 feet per minute.

Tinning 30 No. 22 iron wires traveling at the rate of 320 feet per minute.

Porcelain enameling 60 bath tubs per day, and 50 auto names plates per hour.

Hardening 30 planer knives, 2½ in. x ½ in. x 33 in. per hour at 2,350 Fahr.

As to the industrial scope of the electric oven or furnace the following outline is elucidating:—

Drying.—Varnish, lumber, paper, moulds, plastic forms.

Baking.—Bread, cereals, enamels, cores, transformers, motor windings.

Coloring.—Nails, wire, wire cloth, stampings and metal parts.

Annealing. — Wire, tools, machine parts, brass stampings, silverware, white metal stampings, castings and other metal parts.

Hardening.—Steel tools, bearings, wire, springs, drills, both high speed and carbon, reamers, milling cutters, lathe tools, taps, dies, saws, knives, etc.

Preheating.—All types of high-speed tools.

Porcelain enameling.—Bath tubs, kitchenware, stove parts, signs, lodge and fraternity pins, etc.

Heating.—Automobile rims for shrinking on felloes.

Burning.—Carbon electrodes, manufacture of graphite, china, porcelain and clay products, bank notes, parimutual tickets, general incineration and cremation.

Metal coating.—Tinning or galvanizing wire and other metal products.

Melting.—Solder, lead, soft metal alloys, zinc, tin, brass, copper, bronze, iron, steel nickel, chromium, vanadium, tungsten and other alloys.

Forging.—Steel and tungsten.

Miscellaneous.—Soldering iron heaters, hot plates, plating and cleaning baths, water stills; laboratory furnaces and dental furnaces.

Application to Soldering

Electric soldering furnaces are among the most recent and useful applications. Here, again it has been demonstrated by actual test that the cost is less than gas. Records in one case show an hourly consumption of 840 watts. To bring the furnace up to a required temperature of 1,200 degrees Fahr., takes from ½ to ¾ of an hour, and a pair of 1½ inch coppers may be heated as desired in three minutes. The dressing and cleaning of coppers is no small item in extensive soldering operations, and with electricity it may be done in one half the time consumed where gas is used. Then, again, working conditions are greatly improved for there is no objectionable heat, and obnoxious fumes are eliminated. While the difference in operation costs, so far as actual consumption of electricity and gas is concerned, is slightly in favor of the form-

er, other conditions give it a decided advantage.

An outstanding instance of economy has to do with the use of electricity for drying purposes in lumber mills, when they happen to be within a hydro zone. At night, while the mill is inactive, the available power may be used, say at 1/6 of a cent per kilowatt, in connection with the drying kilns, thus converting chargeable load to useful purpose and eliminating fuel costs otherwise necessary.

Electricity, it is found, has also its advantages in heat-treating dies and punches, as not only being economical but much cleaner than old methods. The product is practically free from scale of any kind and this is most desirable. Many large tool rooms are adopting the idea.

EXPANSION IN TRADE LOOKED FOR BETWEEN CANADA AND WEST INDIES

DISCUSSING, with Canadian Machinery, some aspects of the recent visit to the West Indies of the party of Canadian manufacturers, Sir Alexander Bertram (John Bertram & Sons Co., Ltd., Dundas), states that while the island of Jamaica is an agricultural one, and does not present a large field for the sale of iron and metal products, development has only started which should lead to a gradually widening trade with Canada along lines that are now more or less limited.

The only manufacturing activities are confined to a few sugar mills. These mills were built in England. When the mills were sent out a lathe, a planer, drilling machine and bolt cutter were sent out to each mill. The construction of the mills is such that very little maintenance work is required. Probably the babbitting of a bearing is all that is ever done. Thus the market for machine tools in this connection is practically nil.

Jamaica is about the only island in the British West Indies that has a railroad. This road is owned by the British Government and operated for them by a commission. Naturally as British capital constructed the road, the railway shops were equipped with British machine tools.

These two lines of endeavour represent the only markets for machine tools.

There is, of course, a certain amount of machinery in the hands of private owners, but it is relatively small. Throughout the island the Whitworth form of thread is used. The white population is the only section that uses iron stoves and ranges for cooking. Public utilities, as we know them, do not exist. The country is progressing rather rapidly and is interested in hydro-electric power development and in many other lines of engineering .

There is a fair market for sheet metal products, enamelled ware and such lines. In fact, Canadian goods in these lines are well known. As the population is largely colored, the bulk of the demand for any commodity comes from this portion of the people. In boots and shoes, textiles, etc., only a cheap quality is required. Everywhere there exists a keen desire to trade with Canada. Those lines such as potatoes, flour, fish, butter and cheese, etc., that it is necessary to import, are purchased largely in Canada.

Canadian banks control the finances of the country, but the denominations of currency are the English pounds, shillings and pence. The rate of exchange is practically the same as that of English funds.

The black population is of high intelligence and there is a movement on foot to establish one or more technical schools. General Bertram delivered a good many addresses in the Jamaican Legislature and on other public occasions, and brought to the attention of the authorities, the high class of Canadian machine tools and other apparatus that goes into the equipment of a technical school. The General feels confident that these schools will be equipped by Canadian firms. He also gave several lectures on Canada, describing the railways, canals, ports, hydro-electric developments and other Canadian engineering features from coast to coast. The interest taken in this subject was surprising, and the limited number of views available were studied carefully. The Canadian Trade Commissioner, Major Stephens, formerly a newspaper man, is doing excellent work for Canada. It is believed that the visit of the Canadian manufacturers did more to favourably advertise Canada than has been accomplished in this line for years.

The development of the country has only started, in many ways. If the trip of the manufacturers is followed up in the future with other efforts to foster trade, results will be felt in an increasing trade with Canada in ever widening lines. In the last two years, the trade with Canada has doubled, and the variety of imports is widening every year. General Bertram says that the future of this trade lies in the hands of Canadian business men and Canadian manufacturers. It cannot be built up faster than the colonies grow, but to maintain and develop the connection, these countries must be given more attention.

Tinning 22 wires traveling 320 feet per minute by electric furnace in plant of Laidlaw Bale Tie Co., Hamilton.

Practical Ideas From Practical Men

HOW TO CLEAN AN INDICATOR QUICKLY

By W. F. Schaphorst, M. E.

A short time ago I read an article on the care of ammonia refrigerating machine indicators. According to the author it is possible and permissible to use brass indicators on ammonia machines but they must be used continuously for not too prolonged a time, and after using must be carefully cleaned. After reading this article I was reminded of a cleaning kink that was taught me by a friend who was a chemist. He caught me one day while I was carefully wiping dirt and grease off of some small polished metal parts. He watched me for a while and asked, "What are you trying to do?" "Get this dirt off," I replied. "Why don't you put 'em in a pail of soap and water and boil 'em?" "They'll get wet," I said, "and then I'll have to dry them. After cleaning I want to grease them so that they won't rust." "Very simple," he informed me. "After boiling, rinse in plain hot water, and then dip in the purest alcohol you can get. The wetness will evaporate off in a jiffy and they will be ready for greasing almost immediately."

DRILL PRESS RECESSING TOOL

By I. N. B.

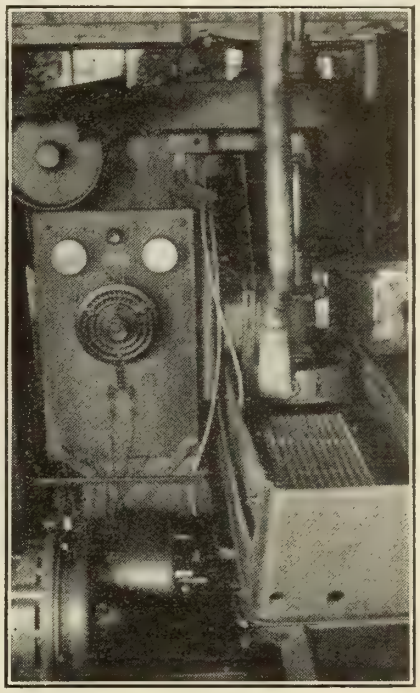
Having the occasion to recess the bottom of a number of ⅜ in. holes it was decided to do the operation in a drill press. The accompanying sketch shows the design of tool made for the purpose. The tool holder A is carried by the shank B, the latter being slotted to receive the holder which is pivoted on the driving pin C. The upper end of the tool holder is provided with an extension D that passes through a slot in the shank and bears on the taper portion of the bush E. This bush is forced down by the action of the spring F, pressing against the two washers G, and H. The handle I is hung from the piece J, that extends down from the collar K, the forked end being provided with pins that enter the groove L. When turning in a normal position the tool M revolves freely in the ⅜ in. hole, but when the lever I is pressed downwards the bush E moves upward and the taper causes the tool holder A to swivel on the pin C so that the cutting point of the tool cuts the required recess.

FEATURES OF A SURFACE GRINDER INSTALLATION

By D. A. Hampson

Shops in rural sections, and in many of the largest cities, are supplied with alternating current. Direct current has certain advantages not readily secured with "a c," among them being speed regulation and electro magnet usage. But day in and day out, the average shop does not miss these direct current advantages—it is only the occasional job and the special application that bring to mind the existence of them. In the slump days following the war, one shop bought some machinery from a defunct concern and among the tools was a Pratt & Whitney surface grinder. There was a Walker magnetic chuck on the machine but the intention was to remove this and apply mechanical clamping devices such as were already in use on less modern equipment in the shop. There was no direct current in the town anyway.

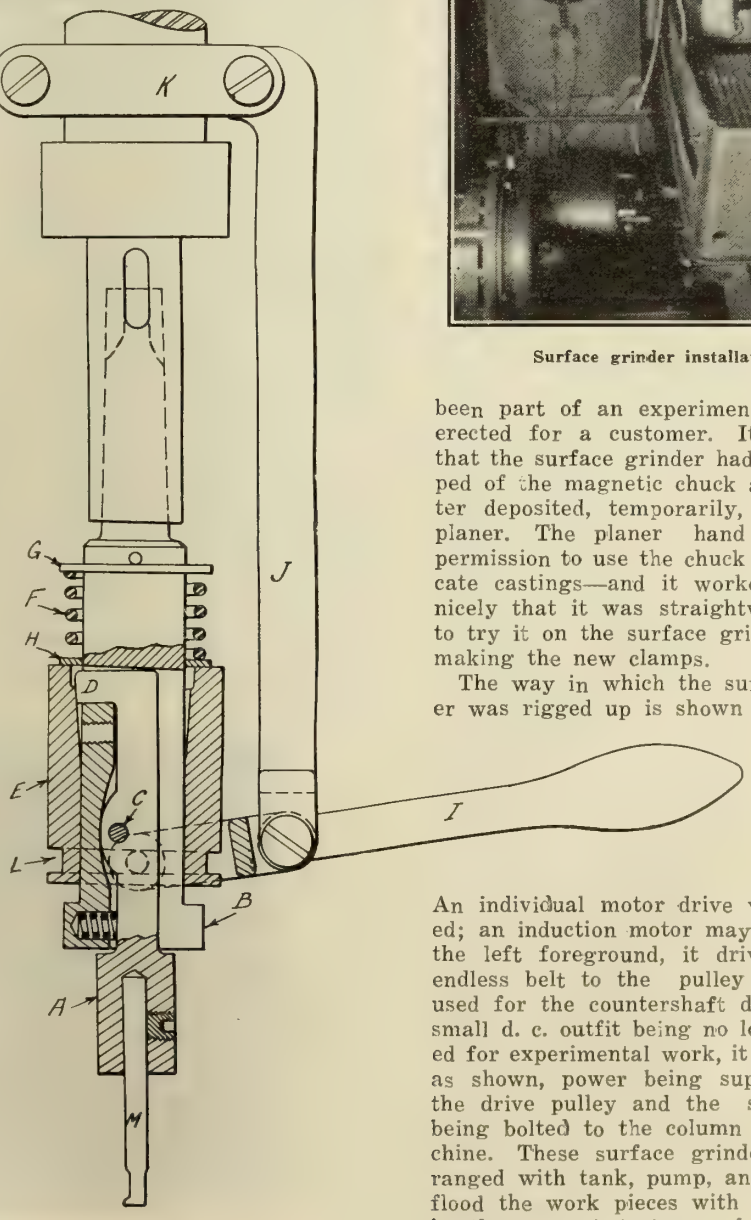
About that time, the shop ran into a planing job on some light cast iron pieces. This was to be done on the small planer which was near the assembling floor and which was near to a small dynamo and switchboard that had



Surface grinder installation.

been part of an experimental machine erected for a customer. It happened that the surface grinder had been stripped of the magnetic chuck and the latter deposited, temporarily, near the planer. The planer hand requested permission to use the chuck on his delicate castings—and it worked out so nicely that it was straightway decided to try it on the surface grinder before making the new clamps.

The way in which the surface grinder was rigged up is shown by the cut.



An individual motor drive was installed; an induction motor may be seen in the left foreground, it driving by an endless belt to the pulley ordinarily used for the countershaft drive. The small d. c. outfit being no longer needed for experimental work, it was set up as shown, power being supplied from the drive pulley and the switchboard being bolted to the column of the machine. These surface grinders are arranged with tank, pump, and piping to flood the work pieces with coolant but in the present instance, dry grinding

was imperative for several reasons. Advantage was taken of this to strip the back of the machine of these unused parts and to bolt rails across the top of the tank space for the electrical equipment to rest upon. The 7½ h. p. driving motor is on a sliding base which rests on these rails and the 1 h. p. dynamo is permanently fixed.

How well the machine produced may be stated when it is told that the other grinder—the one this was to "help out"—has been scrapped and the P. & W. machine with magnetic chuck now handles over twice the highest previous output and runs only part of the time to do it. No mechanical clamp could be as efficient as the chuck. In the photo, there may be seen a load of thirty pieces 1 in. x 10 in. on the chuck. There is a grinding rim one-quarter wide all around both sides and an ordinary helper has ground as high as 3,000 complete pieces in ten hours. For the comfort of the workman, the table shields are used, high all around, and a direct line to the exhaust blower is carried to the abrasive wheel. Surrounding the latter, in place of the usual light sheet metal splash band, is a welded ring of ¼ in. steel, riveted to stout brackets that are adjustable vertically. An oval opening is cut in the ring in the region where the most dust collects and here the 3 in. exhaust pipe is flanged and riveted tight.

X-RAYS AND THE FATIGUE OF STEEL

By E. C. MacCormac

Someone has said "an art is the practice of a science. The greater the art the more automatic its exercise. Engineering was originally defined 'as the art of directing the great Sources of Power in Nature for the use and convenience of man.' This is still an adequate definition of an art now so comprehensive in scope and related to so many activities and interests of mankind that it may be termed the art of arts in this civilization. No other department of human knowledge has advanced so rapidly during the last hundred years. It has transformed human environment in all countries, changed customs, altered international relationships and modified even the physiology and mentality of peoples. By the control and direction of the energies of nature external to man, engineering has developed."

Take for instance the fatigue of steel. Not infrequently serious machine tool and other accidents occur which result in heavy losses in limb and life because some of the metal parts used in the construction of the machine tools, etc., have become so tired that without warning or outward evidence of portending collapse, they have presented perplexing and puzzling problems to the engineering fraternity, which has resulted in a considerable amount of research work in order to reduce the risk connected with metal fatigue.

On investigating a broken crankshaft from a ten ton ammonia refrigerating machine it was found that the material proved to be inferior, in that it was decidedly porous and showed evidence of not having received sufficient reduction in forging. The break which occurred was in the nature of a fatigue failure, and had its origin in the angle between one of the throws and the bearing. A defect at this point had been filled in previously with arc-fused metal. Such a procedure would not necessarily lead to failure had the defect been located elsewhere, but at the point in question the stresses are much higher than at other points on the shaft, and the break once started would be propagated rapidly owing to the unsound character of the steel.

INTERESTING PLANER JOB

In all work-shops of the type which contract for the building of a multiplicity of sizes of machines, there occasionally comes along a job for machining beyond the capacity of the largest shop machine tool available. This situation common enough in its way is nevertheless one which calls into play all the latent initiative in the master mechanic, and its successful manipulation often means the difference between a profit and a loss on the particular piece being handled.

Such a case is the one illustrated by the accompanying photograph. The two halves of a long bed required machining to exact dimensions and as they eventually had to mate up into exact alignment it was desirable, if at all possible, to machine them side by side at the one operation. To secure this result the top portions of the two halves of the bed were first planed to size, and then carefully set up at right angles to the line of the planer travel on heavy box parallels bolted to the machine shop floor. The whole success of the job was of course dependent on the accuracy of this setting up, which, however, did not present many difficulties when checked with a good spirit level.

The tool box used was detached from the planer cross rail, and fitted to a spare chest iron column which was available from off an obsolete design of machine tool. This tool box column was set up at an exact 90 degrees to the finished portion of the bed being operated on, and on the table of the planing machine being set for the correct stroke the operation proceeded without any hitch, the machine attendant meanwhile standing on the planing machine table. The measure of the efficiency of all such rigs is of course the resultant accuracy obtained in a reasonable time, conditions which were adequately met under the circumstances above described.

BOOK REVIEW

Production Engineering and Cost Keeping is the title of a new book by Wm. R. Basset and Johnson Heywood, published by the McGraw-Hill Book Co. The treatise has been prepared especially for production managers, heads of planing departments, foremen and cost accountants; it takes the principles of scientific management and applies them in simple, every day language to the conduct of machine shop practice. The material contained in the book has been developed in the course of years of actual installation of production and cost keeping systems, and the principles and practice treated are highly recommended by the authors.

Two distinct but closely related fields—production engineering and cost accounting—are covered in the book. The first portion is devoted to production planning methods, and the machine shop executive will find the pages in this section full of practical suggestions that will aid him in checking up on manufacturing methods in use and in proposing improvements. The second part dealing with costing methods shows the close relation existing between profitable manufacturing and sound cost keeping. The authors show how properly prepared statements can be made to give an accurate picture of the business at all times, and how they can be used to obtain manufacturing economics and betterments. The book is 6 x 9 inches, 311 pages, and is illustrated with 117 forms and charts, Price $3.50.

Interesting planer job.

Some of the Factors Entering Into Power Cost

Charges Based Either on Cents Per Kilowatt Hour or Per H.P. —Comparison of the Different Systems—Measuring the Power Factor—Taking Peak Average

THE manufacturer's cost of power in many cases only amounts to the equivalent of petty cash, and has therefore during prosperous times received very little consideration. However, due to competition, the manufacturer to-day is watching very carefully the items of his petty cash and should in turn take a greater interest in his electric power bill and understand something of the factors which enter into its makeup.

A Canadian manufacturer's bill, generally speaking, is based on one of two methods. 1. A charge of so many cents per kilowatt hours only. 2. A charge per h. p. of demand, plus a charge per kilowatt hour.

Ten years ago, practically the only method in Canada was No. 1, but the power companies came to realize that there was a difference between the customer who used 24 kilowatt hours in one hour and the customer who used 24 kilowatt hours spread over 24 hours. The difference being that the first customer used 24 times the amount of machinery as was required for the second class of customer and in turn the fixed charges would be 24 times as much in the one case as in the other. An illustration with which we are all familiar, is the summer hotel. Their rates are always high in view of the service they actually give because they have to pay all the interest charges in a matter of one or two months, instead of spreading it over the whole twelve months as is the case with any hotel in the city.

Now let us consider for a moment what fixed charges represent to a distributor of power. These charges naturally cover the interest on investment on the building of the power station, the construction of canals or reservoirs, the installation of water wheels and generators or steam engines and generators, the building of transmission lines, transformers, etc.

It is an interesting fact that the interest on the building of a water power plant, including the items shown above, represents approximately 85 per cent. of the total cost of supplying the power; in the case of steam, approximately 45 per cent. of supplying the power.

Thus it is readily understood that if one customer requires 24 times the amount of fixed charges for the same number of kilowatt hours, his bill should be greater than the second class of customer mentioned.

The result of the realization by the suppliers of power, of the importance of this factor, led to the second method of charging, i. e. h.p. of demand plus kilowatt hours used. The only real difficulty was there was no instrument at a reasonable price available for the measuring of this factor. Therefore except on large customers (where valuable instruments were economically possible) the total h.p. of the machinery installed was adopted as the basis upon which to determine the h.p. of demand and this system which is fairly well known i. e. the "installed capacity" became quite general.

This system however, was not ideal for the folowing reasons. Some manufacturers will put in motors larger than necessary in order to provide for the future. Others have grown so rapidly that they have motors very considerably overloaded. The installed capacity basis penalizes the first class of manufacturer and gives the second class of manufacturer something for nothing.

Another difficulty is that the driving of individual machines is now considered the best practice from an engineering point of view, but if all the individual motors are totalled up, the installed capacity is quite high compared to the actual amount of power taken at any one time. Thus, although the manufacturer is adopting the best practice he will again be paying for more than he uses. Also the manufacturer would pay just the same, as far as the demand portion of this bill was concerned, whether he was busy or slack. Whether he had motors running or idle.

As a result of these conditions a very definite demand was created for instruments at a fair price which would measure the demand portion of a bill. Such instruments have been on the market for some considerable time and are coming into very general use and it may be of interest to give some of the characteristics of their operation. Such instruments take the average of the peak for say 10 or 15 minutes and are so arranged that they push a pointer upwards on the scale. If, for instance, the maximum to-day is 10 h.p. averaged over a 10 or 15 minute period, the pointer will read that amount. If next week the average increases for any 10 or 15 minute period to 15 h.p., the pointer will be pushed up and will remain at that point. An illustration of what is meant by the average over a 10 or 15 minute period makes this point quite clear. Your motor car may have reached for a few moments a speed of 35 miles an hour, but the average speed for a period of 15 minutes will be only 20 miles per hour. In electrical terms your motors may pull 35 h.p. for a few seconds, but the average load or demand over a 15 minute period is only 20 h. p. and 20 h.p. is what the bill would be based on for the demand portion.

ELECTRICITY IN G. T. R. SHOPS

(Continued from page 31)

Hydro-electric power is used largely in Montreal, and in the case of the Grand Trunk shops the cost of current necessary to operate one outfit for one hour is only a fraction over one and one-half cents. Voltages and amperages vary, but in this shop eighteen volts is considered standard while the current runs from one hundred to one hundred and twenty-five amperes.

One of the uses of electricity in the Grand Trunk shops, that has proved very efficient, is that of heating rivets. A rivet heater manufactured by the Humil Corporation of New York City is installed. Five rivets are heated at once. One boy operating the heater can supply two gangs of rivetters. Without undue effort three hundred and fifty to four hundred rivets an hour can be heated. There is no danger of burning rivets and perfect control is obtained with practically no attention. There are no delays due to dirty fires, poor control or other causes more or less common to coal, oil, or gas-fired heaters.

In round house work the Grand Trunk have usually operated their turn tables by air engines. Turn table centres are very inaccessible and dirt, water, and foreign matter usually find their way there, causing the table to be operated with more or less difficulty. When the pressure in the air line was low, due to any one of many reasons, the air engines often got hard usage and the result is that they did not stand up to the work as well as might be expected. Thus it was decided to apply an electric motor to the job. The first motor to be fitted up for this work was recently shipped from the Pointe St. Charles shops to Windsor. A fabroil spur pinion was placed on the armature shaft of the motor, which is a d. c. machine. This pinion runs into a cut tooth steel spur gear and thence through a train of spur gears. The motor was completely covered with a galvanized sheet metal housing which is weather proof, but yet provides for ventilation and has ample inspection facilities. A trolley car control was attached to the motor and it is believed that much better service will be had from this apparatus, than was had from the air engines.

In these shops new construction is handled as well as repair work, and the few uses of electricity mentioned are some of the more important. Portable tools such as grinders are used to a limited extent. At present the air lines are very complete, and there are more air-operated portable tools than electric operated.

New Things in Shop Equipment

DIE-MILLING MACHINE

A machine for milling dies and similar kinds of work of irregular outline and which contains many interesting features has recently been developed and placed on the market. The spindle of the machine operates at a speed of approximately 300 r.p.m. The speed change gear box provides four changes of spindle speeds ranging from 281 to 926 r.p.m. The spindle is provided with a lever operated collar that grips the cutters firmly and yet releases quickly and easily. A number of collars are provided with the machine, ranging from ⅜ inch to 1 inch in diam. The cutters may be held so as to permit of any degree of draft. The double sliding carriage has a traverse movement of 12 inches and a cross movement of 4¼ inches. Dies ranging from 3½ to 17½ inches in width and of any length may be clamped to the table. The slides of the table may be operated independently and in conjunction with each other. Graduated dials on the operating screws permit of very close adjustment. A force feed oiling system provide for the lubrication of all moving parts. These machines are manufactured by the Billings and Spencer Co., Hartford, Conn.

ELECTRIC INDUSTRIAL CRANE TRUCK

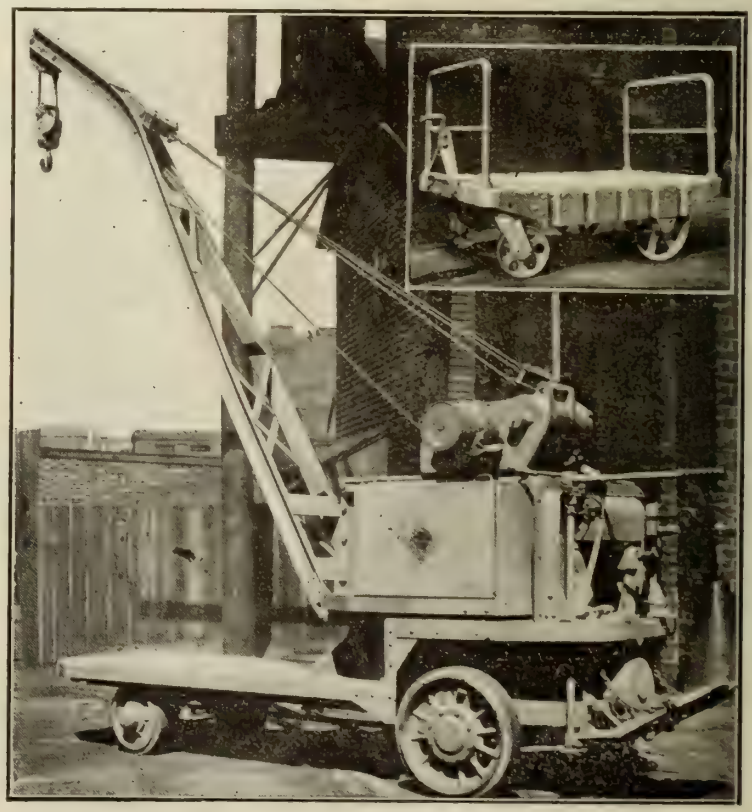
The latest unit added to a line of industrial trucks consists of a low revolving and luffing electric crane mounted on an electric load carrying truck. The capacity of this unit is just less than that of the industrial gas or steam locomotive crane, and on account of the size and flexibility of the unit, it is especially suited for inside, although it may be used for out-of-door service. Lift capacity 3,000 pounds at 6-foot and 1,000 pounds at 12-foot radius without outriggers. Stacks 12 feet high with boom set to lift 3,000 pounds at 6-foot radius. The truck itself is a complete new design of very heavy construction to provide stability and absorb the strains imposed when lifting. The same rugged construction assures satisfactory performance when carrying a ton and a half load, which with truck weight is 8,500 to 9,000 pounds.

An entirely new design of single motor double drum hoist unit handles a separate line to boom and hook. Motor hoist unit with battery in its compartment forms a counterbalance for twelve-foot boom with load. The crane column is supported on heavy, broad pillars and revolves on large ball and roller bearings. A geared revolving or slewing device swings crane through 180 degrees. Boom may be raised or lowered, or swung to right or left and locked in any desired position. With boom lowered, it will pass through a six-foot doorway. A single battery furnishes power to propel, as well as hoist motor. Both controllers are in front of operator. To avoid swinging or twisting of electric cables, they are brought up through crane column. There are but two motors on this equipment. Wide spread driving and trailing axles carry solid, press-on 22 inch x 4½ inch and 15 inch x 3½ inch tires respectively. All standard safety features, as crane trip switch, truck automatic control, worm drive, four-wheel steer and pressure lubrication system are incorporated in this new tool. This is one of the largest capacity electric industrial crane trucks built. It is manufactured by the Elwell-Parker Electric Co., Cleveland, Ohio.

WHEELED-PLATFORM-TRAILER

A wheeled-platform-trailer, designed especially for use interchangeably with Elwell-Parker electric elevating platform trucks and tractors, has recently been placed on the market. This trailer has load carrying capacity of 6,000 pounds and weighs 600 pounds, making it one of the lightest equipments for this capacity yet designed. The construction is extremely sturdy, and the very latest engineering practice has been incorporated in its design. The main top platform consists of a pressed, corrugated open hearth steel plate with deep aprons on either side, making a very substantial support for the load, and when considered together with the heavy 4 inch longitudinal channels all tied into malleable corner castings, a very light yet strong construction is the result. Two long steel caster fork pillars carry graphite bushed bearings at upper ends, ball swivel bearing and roller caster wheel bearings are retained in deep recesses in malleable corner casting. Fixed wheels on roller bearings are carried in forged steel yokes, riveted to top and side. All bearings are provided with pressure lubrication—casters are 10 inches in diameter and fixed wheels 15 inches in diameter. End or side standards with coupler are provided.

When used as trailers, the unit is furnished with hook or eye couplers or with "Y" or "X" chain couplers. When desired, the wheeled-platform will be equipped with 4 casters instead of 2 wheels with 2 casters. When required wheels may be equipped with 10 and 15-inch solid rubber tires of the press-on type; that is, the same as used on electric trucks and tractors. When the wheeled-platform is used with electric lift trucks, clearance has been provided between the wheels in order that the



Elwell-Parker industrial crane. Insert—Wheeled platform trailer.

lift truck platform may be driven beneath. When the lift truck lifts the load, the weight of same is supported on the truck platform by 2 longitudinal channels beneath the wheeled platform. These equipments are especially useful for the transport of materials at shops, warehouses, railway and steamship terminals. They are made by the Elwell-Parker Electric Co., Cleveland, Ohio.

BENCH GRINDER

In the construction of bench grinders it generally is necessary to incorporate a motor approximately as large in diameter as the grinding wheels to obtain the desired operating power. Such a motor sometimes interferes with the grinding operation, especially in handling work that must be fed past the wheel, or in grinding various types of tools. This difficulty has been overcome in the grinder shown in the accompanying illustration. It is equipped with a squirrel-cage, induction motor with the windings at the rear only,

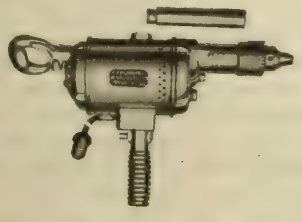
Forbes bench grinder.

which leaves ample space between the two grinding wheels for the easy manipulation of the work.

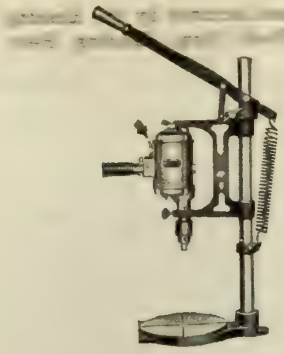
The machine accommodates 6-inch wheels which project 1¼-inch beyond the motor casing. Thus it is possible to utilize three-fourths of the material in the wheels before they are worn to a level with the motor. The design also makes it possible to grind on both sides of the wheel. The grinding wheels are protected by ample guards, while the tool rests are flat steel, adjustable in two directions. The spindle is ¾ in. in diameter, operating in ball bearings. The wheel flanges are of large size, while the motor and bearings are enclosed. The motor develops ½-horsepower at 3,600 revolutions per minute operating on two, on three-phase, 60-cycle current for 110, 220, 440 and 500 volts. The grinder is made by Forbes & Myers, Worcester, Mass.

BALL-BEARING PORTABLE ELECTRIC DRILL

A new light weight ball bearing portable electric drill designed for the particular use of garages and auto repair shops has recently been placed on the market. The new drill has a capacity



Portable electric drill.



Bench drilling stand.

of ½ inch in steel. It weighs only fourteen pounds and carries a universal motor for use on either direct or alternating current. The drill is equipped with a Jacobs chuck, an extra detachable side handle and 10 feet of cable with Hubbel attachment plug. A mandrel with a 3 inch x ½ inch grinding wheel to insert in chuck for light grinding, is furnished as an extra. The entire motor frame, switch handle and end handle are made of aluminum. The motor windings are fully enclosed, dirt and dustproof and all working parts are protected. The motor is air-cooled by means of a fan mounted on the armature shaft. High grade annular ball bearings support both ends of the armature shaft. A ball thrust bearing is provided for all end thrust. The chuck spindle is carried by a phosphor bronze bearing of ample size to withstand irregular drilling pressure. The switch is of special patented design of the quick make-and-break type, with 50 per cent. overload allowance. It is enclosed in the handle of the drill and is operated by means of a push button through the handle. Gears of special analysis steel, heat-treated and hardened, are carefully enclosed and operate in grease.

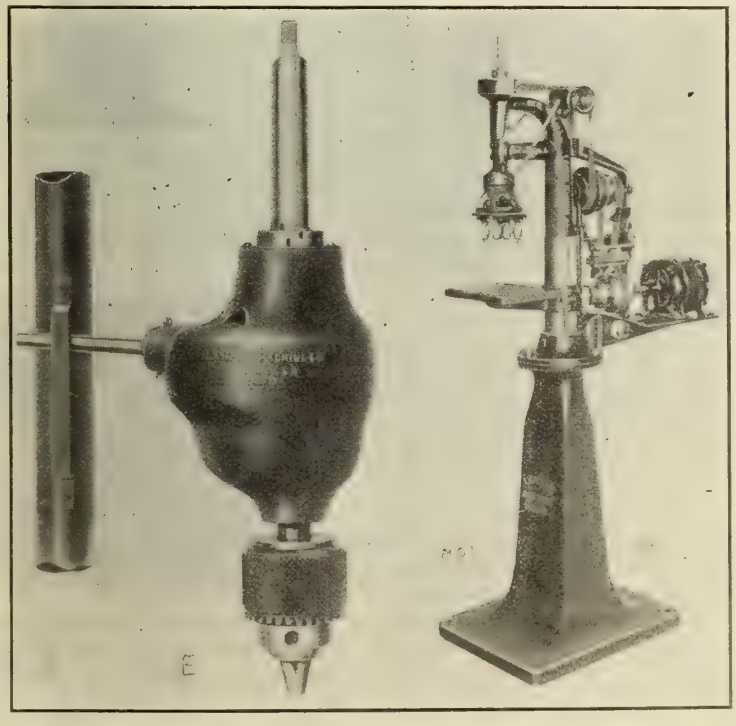
BENCH DRILLING STAND

A special bench drilling stand for use with the new "garage special" portable electric drill has just been placed on the market. The stand makes it possible to convert the drill into a bench drill press in a few seconds time. A cap and thumb screw locks or releases the drill. The stand has a column height of 24 inches, the maximum height from base to drill chuck being eight inches. The diameter of the base is 10 inches. The entire stand weighs 45 pounds. The drill bracket with the drill can be set at any point on the column and raised and lowered as desired. The weight of the drill and bracket is balanced by the spring in the rear of the column. The drill is kept in vertical alignment by means of a key on the bracket and keyway in the column. Depth of holes is regulated by an adjustable stop in the column. The stand is equipped with a lever feed with quick return. This portable electric drill and stand are manufactured by the Cincinnati Electric Tool Co. of Cincinnati, Ohio.

PLAIN AND BACK-GEARED TAPPING CHUCKS

A new line of tapping chucks has recently been offered to the trade. The chucks are designed with a simple friction device for holding taps, so as to prevent breakage, in case a hard spot is encountered in the work. The chucks are made in two styles, one having a tapered shank for use on drilling machines and lathes, while the other has straight shank with a reversing sleeve, so that the device can be used in a turret lathe.

The same firm has also developed a



Back-geared tapping chuck and sensitive multiple drilling machine.

single spindle tapping shank that can be driven directly from the main spindle of a drilling machine. It is fitted with ball bearings and the spindle reverses at higher speed than when feeding downwards. This chuck has a capacity of taps up to ¼ in.

Other models have been brought out where the speed control mechanism and the clutches operate to prevent breakage of the tap in case the movement is hindered by some obstruction in the work. The gearing is entirely enclosed in the housing which gives a perfectly smooth contour. The chucks are manufactured by the Landau Machine & Drill Press Co., of New York.

SENSITIVE MULTIPLE DRILLING MACHINE

A sensitive multiple drilling and tapping machine has recently been offered to the trade. It is of the quick-change type and provides both low and high speeds. Any desired speed can be quickly obtained while operating at full speed. Three drilling speeds are provided, namely 500, 900 and 1,800 r. p. m. Ball bearings are provided for one of the cone pulleys and the eccentricity of the shaft provides for the adjustment in the tension of the belt, while an idler roller is fitted to the machine to take up the slack of the lower belt when the speed is changed. The spindles can be instantly converted to drilling or tapping without adding to or removing any of the parts. Spindles may be operated independently or in conjunction if desired. The entire load of the head is taken by the main drive spindle which is mounted on ball bearings. Nickel-steel, hardened and ground is used for all operating parts, and the mechanism is protected by a ventilated hood which acts as a guard.

The head has a travel of 3½ in., and is operated by means of a rack and pinion. The table is 10 in. x 12 in. and has a vertical travel of 9 in. There is a distance of 8 in. between the spindle and the column. These machines are built by the Landau Machine & Drill Press Co., of New York.

"EVEREDY" ELECTRIC HOIST

An electric hoist especially intended to replace hand power chain hoists has recently been placed on the market. It is rugged in design, light in weight and operates at high speed. The applance is equipped with a mechanical motor brake which operates in conjunction with the control lever. The operating movement of the shifting device is regulated by means of an automatic limit stop that may be adjusted for any desired height of lift. By means of the balancing device lifting hook is always central with the point of suspension. The bearings are protected to prevent loss of oil from the gear casing. The hoist may be controlled by means of pendant cords or by a push button switch. These hoists are manufactured in various sizes ranging from 500 to 4,000 lbs. lifting capacity at high speed. They are manufactured by the Reading Chain and Block Corp., Reading, Penn.

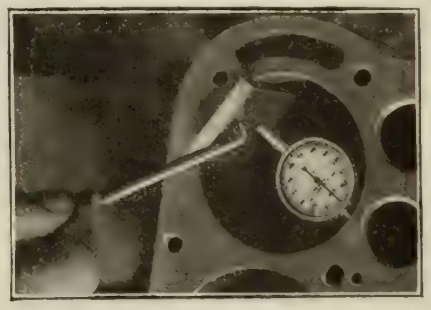
VERTICAL MILLING MACHINE

Recent changes have been made in the Becker No. 2 vertical milling machine. The improvement comprises an auxiliary ball bearing to take the belt pull thus permitting of speed 50% above that formerly employed. The main spindle bearing is of bronze with a babbitt lining. Hard steel thrust washers are used in the spindle. Change of spindle speed is maintained by means of two separate pulleys one three inches and the other five inches in diameter. The change of pulleys is obtained by simply removing one pulley from the speed and placing on the other. It is claimed that the machine operates successfully at a speed of over 6,000 revolutions per minute; this being made possible by means of ample oiling facilities and accurate balancing of the spindle and parts. When operating at the high speed a canvas belt is employed. These machines are manufactured by the Becker Milling Machine Co., Worcester, Mass.

MICROMETER INDICATOR

A combined micrometer and indicator dial for dirtct reading of dimensions within the range of the tool has recently been placed on the market. The Atlas micro-indicator piston gauge is an

adaptation of the dial indicator to a bench gauge for rapidly checking the diameter of pistons, piston pins and other cylindrical articles up to and including 6 inches. Variations are in-



stantly shown on the dial; larger dimensions appearing on the steel scale in inches, by sixteenths; smaller dimensions and variations on the dial in thousandths of an inch. When used in gauging cylinders or holes the device is provided with a saddle that assures the gauging points being kept exactly on the diameter in any position. These micro-indicator gauges are manufactured by George H. Wilkins Co., 180 North Market St., Chicago, Ill.

RADIAL DRILLING MACHINE

Some interesting features are incorporated in a new 4 ft. radial drill recently placed on the market. It is claimed that there is a saving of power from 20 to 25 per cent. due to the fact that the lower shaft, bevel gears in column, shaft in column, gears in column cap, outside vertical column shaft and the bevel gears in back of the arm are eliminated. There is also the advantage that in mounting the motor in this way it balances the arm permitting the arm to raise and lower on the column without exceptional strain on the elevating mechanism. An important feature in this radial drill is that the arm raising and lowering mechanism is mounted as a unit on the back of the arm near the motor drive gears and is only in operation when the arm is being raised and lowered. For this very reason this mechanism was removed from the column cap as this meant the constant running of a pair of bevel gears, a vertical shaft in back of the column and a few gears on the column cap as long as the machine is running or the mounting of an extra motor to raise and lower arm. On these machines the screw is stationary. The revolving unit is of bronze and mounted on a ball thrust bearing large enough to carry considerably more than the weight of the arm, head, motor and other details. A safety mechanism is provided to disengage the clutch that operates the arm raising and lowering mechanism at the extreme positions of the arm. The controller is mounted below the motor and on this size machine is within easy reach of the operator. The head has the same features as other styles of radials of the same make: that is the tapping attachment running in oil, back gears and clutches made of nickel steel, heat treated and hardened, helical spindle gears, and all bronze bearings with oil chamber, permitting ample lubrication. Spindle speeds are from 26 to 450 r.p.m. A 3½ horse power motor is required. These drills are manufactured by the Morris Machine Tool Co., of Court and Harriet Sts., Cincinnati, Ohio.

POINTS TO WATCH

(Continued from page 32)

not seat firmly with a few light taps, something is wrong. The practice of heavy blows must not be encouraged, as this tends to destroy the accuracy of the vise and parallels. It is often advisable when using the vise to apply a round bar between the work and the front of movable jaw as this often tends to give a better bearing on the lower supports.

By the use of special fixtures and attachments the shaper may be adapted to do a wide range of work.

Distribution of Fifty Millions

WHAT THE actual work of hydro-electric power development means to the community is strikingly illustrated in the expenditure of the fifty or sixty millions for the construction and completion of the Chippawa plant by the Hydro Electric Power Commission. Some of the beneficiaries of this undertaking may be given. First there is the farmer, who, for a good price, sold the land through which the canal passes; the engineers, mechanics, artizans and laborers in thousands who were engaged in the work; the stone quarries, brick yards, cement mills, steel mills, manufacturers of contractors' equipment, lumbermen and sawmill owners, makers of water-wheels, castings, overhead cranes, electric generators, switchboards, transformers and much other equipment, all of these and many others account for the huge expenditure, and this has no reference to the task involved in transmission of power and its ultimate distribution.

It was the late Senator Nicholls who declared early in 1921 that "after a careful survey of the situation and with some knowledge born of experience, I venture the opinion that in Canada the development of the electrical industry throughout its several branches will result in the expenditure of not less than one hundred million dollars per year for the next three years, which is as far ahead as I have any desire to prophesy."

Swinging in Right Direction

IT APPEARS to be a fact that prices in the iron and steel markets, while assuming an undoubted firmness, will reflect a cautious attitude toward any suggestion of exceptional upward swing. There seems to be an appreciation of the fact that business generally is struggling to a firm footing, and that any untoward factor would cause a return of over-conservatism. This should be guarded against.

Industry has had exceptional experience during the past few years. From unusual prosperity, it has skidded into reverse conditions, and has come out of it all with an ingrained feeling that, after all, it seems best to play safe. At the same time manufacturers have courageously faced the fact that the pendulum must swing back. From time to time there are signs that suggest it is moving smoothly enough, but when things are going well it is sometimes wise to see that the machinery is well served against impediment. That is just what the manufacturer is doing. He wants to be sure that the swing will make the full arc. That is one reason why business is being conducted largely on the basis of immediate prospect rather than future speculation. At that, there is a good foundation for aggressive work. Inquiries are good, showing that there is a mission for advertising with a punch behind it. Indications point to a fine crop, that the building industry in many centres is flourishing, that the growth of motor car demand indicates that an increasing number of people are confident of an ability to buy, large numbers of unemployed are being absorbed, and there are those who predict that the last quarter of the year will see personal work merging nicely into permanent employment. Many industries are taking on more men, even at this, generally the most indifferent period of the year, and it is worth observing that the market generally reports the first half of July as showing an activity that promises a record. From a business point of view the calendar seems to have lost some significance.

Advertising and the Selling Price

WHEN THE chairman of the Manchester Chamber of Commerce recently reviewed the state of trade he made the following interesting comment: "It is becoming a recognized fact that advertisements do not add to the selling price of an article, because overhead charges are reduced consequent on the increase of sales."

This observation presupposes, as a matter of course, that the advertising has been conducted in a thorough and systematic manner; that there has been concentration on the prospective field and that the advertising was used and developed as an active means to an end. Under these circumstances, the chairman merely gave utterance to what is coming to be regarded as part of the gospel of modern business.

The only kind of advertising that can be reliably applied in the offsetting of overhead charges is that which, on the whole, satisfies the management as to its merit as an indispensable adjunct of the sales force. A campaign may be made up of different phases. On the one hand, it may be more or less descriptive of the product and not overly solicitous as to sales. Then, relying upon the fact that through this medium the field should be well informed, the actual sales appeal is made and pushed to the limit.

It is all akin to the method employed in making individual sales for advertising is, after all, nothing but salesmanship in print. Someone has said that "the best place to print an advertisement is on the wagging tongue of a satisfied customer," and that "salesmanship is the power to persuade plenty of people to pleasurably purchase your product, whether it be planers, punches, printing presses, pears, prunes or peanuts, at a profit." When it is so worked out advertising reduces the overhead and helps to stabilize the selling price. The chairman was right.

Special courses for export managers are to be included in lectures at Toronto and McGill Universities, beginning Jan., 1923. Nothing like a well-trained outlook. At the same time what is to be done with the foreign buyer who addresses an inquiry: "Toronto, N. Y., via Erie Canal."

How Strikes Affect Steel Producer and Consumer

Curtailment in Output Now Apparent—Largely Result of Shopmen's Walkout—Some Companies Suffer Little—Consumer Anxious to Fill Book Orders—Producer Conservative With Regard to Future—Basis Prices Remain

PIG IRON ADVANCE IS NOW PREDICTED

THAT the railway shopmen's strike is the more serious factor to the steel industry is evident from the fact that the coal strike started April 1, and the shopmen's strike July 1. The latter, already, has had the effect of tying up the supply of coal from southern coal fields to steel producers. The iron and steel industry increases its output in May and June, the production being at the rate of 36½ million tons a year, while in December the rate was about 20 million tons.

Reports from steel centres in United States show that many furnaces are now being banked or blown out. It is predicted that, as a result of curtailment, steel ingot production will go below 30 million tons a year. Some companies, as yet, have suffered little. The Carnegie steel, for example, has blown out one furnace, leaving 38 in operation.

Who will be affected the more, producer or consumer? It is observed that there are more consumers seeking to buy for early mill shipment at premium prices and also buying from warehouses at the stiff extra over-mill shipment rates and on the other hand, consumers in general display little interest in deliveries for late in the year. This indicates that there will be an attempt made to fill certain book orders promptly. After that, consumers are not disposed to take a chance.

Producers are, on the other hand, show a reticence about taking on orders, and would probably be unwilling to consider fourth quarter business. Regular basis prices remain, but some premiums are being taken on early delivery.

Actual buying demand for pig iron may develop at any time and this would probably cause advances to fancy prices, owing to decreasing production. There is quite an apparent tendency, however, to keep within reasonable price basis, although it is difficult to predict what may happen should the situation become seriously aggravated.

In the Canadian market, at this vacation period, there are very few traces of what may be termed hectic excitement. For this time of year business is good, and once the vacation season is over, the hope is that it will come into a good stride. Construction materials show large tonnages and the prices are stable. Coal strike complications are developing and authorities predict that pig iron may advance $2.00 per ton, due to the coal and coke situation. It is not long since pig advanced $1.50 per ton. The prices, as advanced in iron and steel bars last week, are holding firm.. It may be said of the entire market, that it is showing some evidence of nervous strain, for there are, on one hand, prospects of much better business and on the other, the danger of paralysis due to strikes. There is an optimism apparent, however, largely rooted in the feeling that authorities will find a solution before great harm develops.

Turpentine prices, as previously announced, had a recession last week to $1.65 and in spite of a near famine in turps. this price still holds, though it is claimed new stocks will carry an advance.

Machine tool demand continues dull. It is a fact that some business is moving, representing absolute necessity and in small tools and supplies there continues to be a fair volume though it is quite below desired strength. The trading or exchanging factor is quite an important one to deal with at the present time. It is often the case that the prospective buyer has something to offer as exchange on a new deal, but it is evident that the proposition does not go through unless it has merit as dealers seem to be about fed up on anything that does not look like good, straight legitimate business.

Montreal reports a continuance of good business in galvanized sheets, merchant bars, structural steel, small steel products and miscellaneous lines. The fear that the coal and rail strike may drag along for some time without satisfactory settlement is causing some apprehension, for supplies are getting low and business seems inclined to quite an improvement. In fact, it is felt that July may be almost as good as June. Competition of Scotch pig iron with the Canadian product is said to be developing into a competitive factor in quarters adjacent to ocean shipping, and there are those who declare that it is a fixture on the Canadian market.

There has been very little doing in machine tools, while in machine shop supplies, a good amount of business is moving, though buying appears to be from hand to mouth.

Toronto

July 26

AGAIN there is a likelihood of an increase in pig iron. The cause is said to be the coal and coke situation and the fact that the industry is confronted by conditions over which it has little control. Furnaces are advising buyers of the likely development. A boost of $2 a ton is spoken of and the movement is but an indication of the way things are going in the United States. An announcement that the strike situation is well in hand, and that some drastic action is being taken to relieve the situation would have to be considered as a better price factor by the producers.

Non-ferrous metals are firmer, but the Canadian demand is said to apply mainly to small lots. The situation is one that may be described more or less as in the nature of a see-saw. Fluctuations have been frequent and insignificant and indicative of general conditions. It is interesting that one year or more ago, tin was cutting up some remarkable antics, advancing or rising pounds sterling per ton. This was also at a time when Canadian money had a larger buying power than at present in the English market, and the American exchange was around 12 per cent. To-day tin plates are about stationary, daily reports indicating very little tendency toward change. Prices follow:

Lake copper	17 00
Electrolytic copper	17 00
Castings, copper	16 75
Tin	34 00
Spelter	7 50
Lead	7 00
Antimony	7 40
Aluminum	21 00

Scrap metal markets remain quiet. The demand is not only light but the supply seems to be somewhat on the short side. American sources for certain grades are quite reticent following the general tendency, and this is not altogether regarded as an attempt to make the most out of the coal and rail strike situation. Business has been struggling too long to expect any branch of activity to hinge on opportunity for price manipulation upon the present labor crisis. Though there is little moving in old material, therefore, prices show a firmness, reflecting problems of supply. Prices follow:

	per 100 lbs.
Copper, light	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper Wire	11 00
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	4 85
Light brass	3 50
Medium brass	4 50
Scrap zinc	4 00
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	11 00
Axles (wrought iron)	16 00
Rails (scrap)	11 00
Malleable	11 00
No. 1 machine cast iron	16 00
Pipe, wrought	6 00
Car wheel	16 00
Steel axles	15 00

Iron and steel bar lists have now been generally revised in accordance with the recent advance of 10 cts. per 100 lb. The demand is still strong. The sheet situation also reflects the seasonable

activity in building and kindred industries and while prices are fairly stable, the supply of certain kinds is very short. Prices follow:

Iron bars	3 15 to 3 25
Steel bars	3 15 to 3 25
Reinforcing bars	3 15 to 3 25
Steel hoops	4 00
Tire steel	3 15
Spring steel	7 00
Band steel, No. 10 gauge and 3-16 in base	3 65 to 3 75
Small shapes	3 25
Sheets, black, No. 28	5 00
Sheets, blue ann., No. 10	4 00
Canada plates, dull, 52 sheets	4 90
Canada plates, all bright	6 00
Galvanized Sheets, No. 28	6 00

The turpentine situation promises interesting development. The barrel-lot figure of $1.65 as quoted last week, holds good, but there is said to be great scarcity. The prediction is that new supplies will see an advance.

Announcement is made of an advance of 25 cents per keg on cut nails.

Machine tools are showing a little life. Motor car districts such as Walkerville and Oshawa would be dull indeed if they did not occasionally require some new equipment for them and not only the car plants themselves but so-called subsidiaries which figure in demand. The volume is small, but as the saying goes "better than January." Supplies and small tools are still in fair demand.

Montreal

July 26

A VARIETY of conditions, some of them having conflicting influences, have caused an analysis of the local iron and steel market to be a rather complex problem. Last week mills advanced their quotations to the jobbers and large consumers ten cents per hundred pounds base. The jobbers anticipated this movement, and, influenced by the late deliveries from the mills, advanced their quotations two weeks ago. The advances made were somewhat higher than they have been able to obtain, except for small lots. The movement of iron and steel is about the same as last week. Galvanized sheets are the most active, while black and blue annealed sheets are always moving very well. Trading in merchant bars, structural steel, and small steel products, as well as in miscellaneous lines such as reinforcing bars, tire steel, etc., continues good. At the present moment, there is some apprehension felt as to what extent deliveries can be made, should the coal and railway strike assume a more threatening attitude. Pig iron sales continue to be encouraging with a tendency toward weakening in quotations. Machine tools are very quiet as also is the scrap market. Supplies continue to move freely. The non-ferrous metals are about holding their own as far as volume of trade is concerned. Quotations are firm.

Iron and steel—Last week the mills announced that their price to jobbers would be $2.60 base and to large consumers $2.40 base, per hundred pounds. This meant a ten-cent advance. For some time past deliveries have been getting worse from the United States mills. The threatening attitude of the coal strikers, and also the railwaymen, has led the jobbers and dealers to conscientiously believe that there was a real likelihood of their supplies being cut off. Thus quotations rose on the local market to $3, and in some cases for small orders, $3.15, base. But July and August are quiet months in these lines and business, which was very good up until the 10 inst., began to drop off a little. The result is that attractive specifications are getting somewhat lower quotations. Supplies are getting low, and most dealers are concerned greatly as to where they can replenish their stocks. Galvanized sheets continue to arrive from British mills, and are being consumed as fast as they arrive. Standard sizes and gauges are practically impossible to obtain from stock. Other classes of sheets are moving well. Merchant bars, structural steel, and small steel products are still in good demand. The call for tire steel, reinforcing bars, steel hoops, and other miscellaneous products, continues good. It is thought that the figures for July will be nearly as good as those of June, which was the best month so far this year. The local quotations are as follows:

Iron bars	3 15 to 3 25
Steel bars	3 15 to 3 25
Reinforcing bars	3 15 to 3 25
Steel hoops	4 00
Tire steel	3 15 to 3 25
Spring steel	6 00
Band steel, No. 10 gauge and 3-16" base	3 25
Small shapes	3 00

Pig Iron—Sales of pig iron are keeping up. Canadian pig iron is being disposed of very well indeed, in spite of the competition offered in the form of Summerlee iron. This latter iron is always moving nicely at a figure roughly one dollar a ton less than the local product. Summerlee iron cannot meet figures of the Canadian pig iron at inland points, thus the sales of the former are largely confined to points adjacent to river ports. Summerlee is quoted at $29.75 on docks while Canadian iron is quoted at $31.85 on tracks in car lots. It is however, weak at this figure. There is no doubt but that attractive business will get a slightly better figure. The competition from British furnaces is made possible through several conditions. Most ore that goes into British pig iron is imported. These ores are mined in countries where labor is cheap, such as Spain and Algeria. British shipping can obtain cargoes to many remote points and often can make attractive freight rates on the ore, and the pig, because of the fact that British imports are so great and of so wide a nature, that a return cargo is assured. Thus, unless conditions change greatly, British pig will be offered in Canadian markets, indefinitely. One large concern recently purchased a lot in excess of 1000 tons through brokers in New York. The iron was another grade of Scotch pig. The price is understood to be less than that asked for Summerlee. The foundries appear to be purchasing iron at a more satisfactory rate of late. In fact market conditions are gradually improving, and when compared to the tonnage moved at this period last year, are very good.

Machine Tools.—Little or no change has been reported in the machine tool market. Very few sales have been made except for an odd machine here and there. Most dealers feel that very little improvement can be looked for till after the first of September. Inquiries are coming in as much as usual but it is difficult to close orders. Staffs are more or less disorganized on account of vacations, and many executives are absent, so that the dealers feel that, in spite of inquiries they must mark time.

Machine Shop Supplies.—The jobbing and contract shops are enjoying a good share of business at this season, and are coming into the market in a small way, almost continuously for supplies. The railways are operating their shops at better than half capacity and they contribute, in a fair way to this business. Buying still continues to be practically from hand to mouth. The supply business came through the readjustment period much more quickly than other branches of the trade and there is a feeling that requisitions can be filled promptly, and for that reason no shop is covering its requirements except for immediate use. Prices are fairly stable, and the turnover quite satisfactory when all things are taken into account.

Non-Ferrous Metals—The non-ferrous metals are moving in about the same quantities as they were last week. Business is scattered, no large orders being received. Prices are tending toward firmness, and in the case of tin and spelter they have advanced one half and one quarter cent respectively. There has been no outstanding feature during the week, which has, in fact, been very quiet. The local quotations are as follows:

Lake Copper	17 75
Electrolytic Copper	17 50
Castings, Copper	17 25
Tin	35 00
Lead	6 75
Spelter	8 00
Antimony	6 50
Aluminum	23 00

Scrap Metals.—The scrap metal market has also had an uneventful week. No price changes have been noted, and sales have not been encouraging. Holdings by local dealers are small. Some outside business has been done, but the local demand has not increased. The following are the local quotations:

Copper, light per 100 lbs.	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper Wire	11 00
No. 1 compositon	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 00
Light brass	4 00
Medium brass	5 50
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton.	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	20 00
Pipe, wrought	7 00

Pittsburg

July 26

THE transportation situation has caused a material drop in pig iron and steel production, as foreshadowed in this report of a week ago. About the middle of June congestion reached considerable proportions on the railroads serving coal fields in West Virginia and Kentucky, on which the steel industry has been depending much more than usual, on account of the strike at the union coal mines and various non-union strikes, including those in the Connellsville region.

The general strike of railroad shopmen which started July 1 tied up the movement of southern coal almost completely, as to its coming north across the Ohio river, and slowed down various other roads, even including at least one that taps the Connellsville region. Of course, the coal strike is important, in making the iron and steel industry short of coal, but to get the perspective one must remember the coal strike started April 1 and the shopmen's strike July 1, so that the coal strike is between three and four months old while the shopmen's strike is between three and four weeks old

The later is the more important factor. The iron and steel industry got along fairly well the first three months of the coal strike, increasing its production, as in both May and June production of steel ingots was at a rate of about 36 1/2 million tons a year, while the rate at the end of March was about 35 million tons a year and the rate last December had been only 20 million tons.

Furnaces Blown or Banked

The Republic Iron & Steel Company had been operating three blast furnaces at Youngstown, and has had to bank two of these in the past week. It had started its Bessemer steel making department July 5, after an idleness since last September, and has had to close it. The open-hearth department continues as formerly. La Belle Iron Works has blown out the one furnace it was operating, and Trumbull-Cliffs at Warren, O., serving the Trumbull Steel Company, Cleveland, has banked a furnace. The McKinney Steel Company, Cleveland, has banked a furnace. Practically all of this is due to curtailment of supplies of coal at by-product plants that had been using Kentucky and West Virginia coal largely if not wholly. The by-product plants at Buffalo have been getting short of coal. Some of the furnaces in that district are running with slack draft and it is probably only a matter of days until some of them will have to bank or blow out. Cherry valley, a merchant furnace at Leetonia, O., (Mahoning valley) went out a few days ago.

The above sketch is representative, but probably does not cover all the curtailment that has occurred to date. Unless conditions change radically for the better there will be further curtailment. A good guess would be that steel ingot production will go below 30,000,000 tons a year before it goes above the 36½ million ton rate shown for May and June.

It chances that thus far the Carnegie Steel Company has suffered but little. It has blow out one furnace, leaving 38 in operation, but this is stated to have been for necessary relining. The Jones & Laughlin Steel Company is reported as not affected thus far in its furnace operations. The Carnegie Steel Company's ingot output, however, which has risen from about 70 per cent. of capacity in April to 80 per cent. at the end of June is down to about 75 per cent.

The condition of restricted transportation, with the continuance of the coal strike after President Harding's failure to get it settled by arbitration, with an immediate resumption of mining meanwhile, is so new that the reaction of the trade to the condition cannot be fully gauged. Steel shipments are decreased somewhat, with prospects of more decrease to follow, but on the other hand there is the factor that consumers may not have sufficient coal and transportation to operate at the rates they contemplated when they arranged for their steel deliveries. The point really is which will be affected the more, the production or the consumption of steel.

To Fill Orders

What can be observed now is this, that there are more consumers seeking to buy for early mill shipment, at premium prices, and buying from warehouse at the stiff extra over mill shipment prices, while on the other hand consumers in general have stopped showing any interest in deliveries late in the year. The position apparently is that they have certain orders on books which they wish to fill, and fill promptly, even if they have to pay delivery premiums, while they are disposed to take chances on their having business late in the year. As to producers, they are more reserved about taking on obligations and the majority probably would be unwilling to sell for fourth quarter even if buyers were anxious to close. Mills that can make early deliveries are in some cases asking for greater premiums, particularly in bars, shapes and plates, for which up to 1.90c has probably been paid. One mill, indeed, has an asking price of 2.00c on prompt bars. The regular basis price remains at 1.60c the price at which some conservative mills would accept desirable orders for late delivery, but an order must be very good to be considered desirable.

May Attempt to Operate

Since President Harding's plan for ending the coal strike by arbitration failed, through the miners rejecting arbitration, and the President "invited" the operators to go home and resume mining coal, plans have been under way for the attempt, both in the regular Pittsburg district, which has been union and in non-union fields, like Connellsville, where there have been sympathetic strikes. Two mines of the Pittsburg Coal Company, and one each of three other companies are scheduled, are to be formally opened as a test. In the Connellsville region the first effort will probably be by the H. C. Frick Coke Company of the Steel Corporation.

Connellsville coal has been in somewhat lighter supply on account of the fresh strike that followed the efforts at Washington to settle the strike and on account of railroad congestion, while demand has been much heavier, largely on account of consumers being shut off from West Virginia and Kentucky. The market has been advancing sharply, until Connellsville steam coal has reached $7.00, while Connellsville furnace coke is held at $13 and coke supposed to be of foundry grade has brought $14.

With pig iron production decreasing and with consumers presumably out of stocks by this time, pig iron would no doubt advance to fancy prices if there were any actual buying demand, and this may occur any time. A sale of 100 tons of malleable iron has just been made at $27, valley, which gives an idea of the trend. Prices formerly quoted, $25 on Bessemer and $24 on basic and foundry, at valley furnaces have become purely nominal.

RAPID MAKING OF GEARS

Nothing is more striking in recent engineering progress than the development of highly efficient gearing. This development has involved the construction of many wonderfud machines for cutting gears rapidly and with extreme accuracy. One of the difficulties of gear cutting is that so much time has to be occupied merely in cutting away large chunks of metal before the final and careful trimming of the gear is possible. In order to get over this difficulty British engineers have developed machines for gashing out, as it were, the main mass of metal between the teeth of the gear. Heavy cuts of metal are therefore made with great rapidity, and the final process of forming the gear is rendered both easy and swift. A British firm recently produced an improved machine on this system to deal with gear wheels up to three feet in diameter; and it is now constructing much larger machines. The special feature of these machines is the use of two cutters, one cutting on the front only and the other cutting on the sides. In this way three distinct and separate cuts are produced, and the metal comes away with exceptional freedom. The heavy roughing out cuts and the lighter gear-shaping cuts can, in fact, be performed at one and the same time.

BOOKLET

The Charles Parker Co., of Meriden, Conn., has recently issued a new catalog on their line of vises and ratchet drills. This booklet describes and illustrates the many improvements that have been made to their equipment during the past few years. A feature of the Parker vise is the solid steel strenthening bar that extends throughout the entire length of movable jaw.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

PIG IRON

Toronto price:—	
Silicon, 2.25% to 2.75%	$30 65
Grey forge, Pittsburgh	$25 27
Lake Superior, charcoal, Chicago	31 65
Standard low phos., Philadelphia	30 00
Bessemer, Pittsburgh	25 00
Basic, Valley furnace	24 00

News From the Industrial Field

Major R. Crowe, manager of the Crowe Iron Works, Guelph, is attending the Bisley meet in England, as a member of the Canadian rifle team.

National Castings, Limited, Brockville, are installing an electric furnace for both steel and grey iron production.

The private car "Eatonia" owned by the late Sir John Eaton, and which originally cost $100,000 has been sold to the C. P. R.

The Dominion Bridge Co., has secured the steel contract in connection with the $60,000 addition to the dairy buildings at Ottawa.

Toronto Board of Control fearing a coal shortage in that city next winter have recommended to the city council the expenditure of $100,000 on the importation of coal from Wales.

The E. B. Eddy Co., of Hull, Que., are having plans prepared for an addition to their plant; the cost of the building will be approximately $1,000,000.

Maple Leaf flour mills at Welland were gutted by fire July 21. The cause is supposed to have been spontaneous combustion. The loss is estimated at $150,000.

Alfred Herbert Ltd., are appointed sole Canadian selling agents for the mining machinery, air compressors, rock drills and pneumatic tools manufactured by Messrs Holman Bros. of Camborne, Cornwall, Eng.

Aluminum wire, such as used for power transmission purposes is composed of 99 per cent. pure aluminum. It has 62 per cent. conductivity as compared with copper, costs twice as much per pound, but its weight is only one-half that of copper.

Steps are being taken by the Canadian Government for the appointment of a Trade Commissioner and an assistant to investigate and report on the possibilities of opening trade in Mexico. The Order-in-Council containing the authority for the appointments says: "Mexico offers a field for organizing and extending healthy trade relations between that Republic and Canada."

A commutator is that part of an armature which reverses the direction of electric currents in any circuit. It consists of copper bars or segments, side by side, forming a cylinder and insulated from each other, ordinarily by sheets of mica. It rotates with the armature and the conductors of the latter are so connected with the segments of the commutator that the current taken off by the bushes bearing upon its surface are direct although an alternating current is generated by the armature itself.

In order that the conducting capacity of the rails in a trolley line may be preserved they are connected or bonded at their joints by short pieces of copper cable or wire rivetted or welded into the adjoining ends.

Chemical action, may be induced by a ray of light or invisible radiant energy known to science as the actinic ray. Most powerful in this classification are the violet and ultra violet rays of the spectrum.

Kingston.—Tenders are being asked by Stevens and Lee, architects for the new isolation building for the Kingston General Hospital. Plans may be seen at 62 Charles Street, Toronto, or at the office of J. C. Newlands, Kingston.

Alternating currents are described as those which, rising and falling in strength, flow alternately in opposite directions at regular intervals. The currents vary in intensity from a plus maximum to a negative maximum and are separated by points of zero pressure as distinguished from a direct or continuous current.

Kingston.—Another industry is in the offing for the city of Kingston. Stanley and Aylward, Toronto manufacturers of "Norman" silver plate, have laid a proposition before the City Industries Committee. They intend to float about $30,000 of stock in the city and the civic officials have been authorized to offer that amount to the people of Kingston. The new firm may use a building near the Locomotive plant.

Through lack of power industries at Belleville were completely tied up during the latter part of the week. The situation in Peterboro also threatened, when several factories were compelled to shut down. At the latter place the trouble is said to have been caused by restricting conserved waters, causing a difference in levels, but, on the other hand, the cause is attributed to evaporation. Some difference of opinion seems to exist as to water rental per horsepower and the matter is one that has to be threshed out between the Hydro Commission and Ottawa Government. The Department of Railways and Canals ask a rental of $3.50 per horse power, which is claimed to be exhorbitant, and had cut down the supply at hydro stations. As a result industries in several towns are crippled. Formerly, the rates had averaged $1 and $2 and it was claimed that some power concessions in other provinces were securing water from the Dominion free of charge. The Province of Ontario is charging a maximum of 50 cents per horse power.

A manufacturer of machine screw products states: "Business conditions in our line are slowly improving, particularly in special pieces and automobile works. Standard or general lines are gradually increasing as confidence returns, although, as you know the machinery men are not very busy, consequently we cannot expect to be. However there is a general improvement and we hope it will continue."

Dominion Fabrics Limited, is a new corporation, capitalized at $250,000 to work in collaboration with the Dominion Hammock Co., Dunnville, Ont., but under a separate charter. The Campbellford interests which own the entire stock of the Hammock works, are big holders in the new venture. The new structure, which is nearing completion, is of steel built in with brick, 130 feet in length and 58 feet wide, four stories high including the basement. It is the intention to employ an additional 150 hands. The output will include dress goods, curtains, table spreads, etc.

Indicative of the come-back in the motor industry is the report of General Motors Corporation for the six months ending June. Net sales are reported as $218,490,887; net earnings before Federal taxes and interest as $35,116,481; net earnings after all charges as $29,997,391; net amount earned on the common stock $26,839,391.

The indicated production of 271,022 motor vehicles in June established a monthly record. It is estimated that of this number about 10 per cent., or 27,000 were trucks, leaving 244,000 passenger cars, a gain of six per cent. over 231,619 in May, the previous record month. Production of passenger vehicles for the six months to June 30 was 1,016,742, as against 1,514,000 in the full year 1921.

Australia has stolen a march on Canada by entering into an agreement with the British Government under the Empire Settlement scheme. Canadian parliament has prorogued without passing the necessary legislation. The plan as proposed will be operative until March, 1923 and will cost £400,000. There will be a grant to desirable immigrants of one-third of cost of passage, another third will be loaned at a low rate of interest, and even the remainder may be advanced if necessary. Initial allowances may also be granted. Australia, owning its own steamers, will make the expenditures and will be refunded one-half by the British Government. Only immigrants proceeding under settlement or development scheme, or assured of other employment in Australia will be eligible for these assisted provisions

Kingston may use coal from the Maritime provinces for the manufacture of gas.

Fire did $30,0000 damage to the leather goods plant of A. R. Clarke, Carlaw Ave., Toronto. Explosion of a gasoline tank during the fire made control difficult.

Authority to construct a bridge across the Niagara river to replace the old cantilever bridge built in 1882, over which the Michigan Central now operates, has been granted from Ottawa.

Toronto, Ont.—During the month of June construction contracts awarded in Canada amounted to $25,620,400, creating a record month for building in Canada since June, 1914.

Welsh coal may be used to relieve any coal shortage in Canada. Despatchers from Montreal indicate that cargoes are already on their way. Anthracite will be delivered at about $17 a ton.

Carpenters working on the Welland ship canal may strike for an increase of from five to fifteen cents an hour. The men claim that an order from the Minister of Railways and Canals justifies their claim.

In order to investigate openings in Russia for Canadian trade, the Dominion Government has authorized the appointment of a permanent trade commissioner, with an assistant, to that country. Russia may establish a trade agency here.

Fire prevention day has been set by the Government for October 9. Inspection of factories, public buildings, warehouses, theatres, hospitals, and private residences will be required, as well as removal of conditions likely to cause fire.

Saulte Ste. Marie, Ont.—The Algoma Steel Corporation has secured a 48,000 ton rail order from the Canadian Pacific Railway. This means that the rail mill will be re-opened immediately and put in full operation. The work will give employment to 2,000 men and will result in a general stimulation of business locally.

Windsor, Ont.—Wallace A. Campbell, vice-president and treasurer of the Ford Motor Co. of Canada, has officially announced that his company will begin in the near future the erection of a huge motor plant immediately adjacent to the present factory in Ford City. The new plant will cover approximately 125 acres and will cost in the neighborhood of $6,000,000, according to Mr. Campbell's announcement. The new property extends for 2,000 feet along the river front. It is expected that the production of the Canadian Ford will be doubled immediately the new plant starts to operate, and the plans are to turn out 500 cars a day in place of the 250 made at present. This will not represent the entire capacity, however, as the plant will allow a production of 1,000 cars a day, as soon as the market warrants the output.

Calgary, Alberta.—It is proposed to construct a hydro-electric plant on the Bow River, east of the city, to consist of four dams, the first of which will cost half a million dollars. The project is that of the Alberta Hydro-Electric Company, Ltd., of this city.

Vancouver, British Columbia.—Ocean borne lumber exports from British Columbia mainland for the first six months of the year show an increase of 21,737,-745 feet over same period last year. Shipments totalled: shingles 128,934,-500, box shooks 164,948 bundles, lath 12,220 bundles and lumber 94,552,742 feet.

Vancouver, British Columbia.—Tenders are being called for the superstructure of the new pier the Canadian Pacific Railway is constructing here for the accommodation of its ocean liners. The new work, which is the largest the Canadian Pacific has undertaken locally for some time, will give employment to several hundred men for approximately twelve months. The pier is to be 850 feet long and 330 feet wide, and is estimated to cost about $2,000,000.

St. John, New Brunswick.—it is reported that a Canadian engineer working for a St. John syndicate has made a number of valuable mineral discoveries in North Cumberland County, which include gold quartz, sheet mica, graphite. and clay or paint. The gold, it is claimed, should assay one ounce to the ton the deposit being only about 200 yards from the railway. Samples of true sheet mica from one foot to three feet square were brought out. A fine clay or paint was uncovered running in a deposit over one and a half miles long in layers of blue, light and dark yellow, bright scarlet, Indian red and pink, pure white and jet black. This deposit is seven miles from the railroad.

LITTLE COAL ARRIVES AT LAKE HEAD

Fort William.—The serious aspect of the fuel situation in the United States, and its resultant effect upon Canadian industry, is becoming apparent here. Usually at this time of the year coal cargoes are arriving from Lake Erie ports at the rate of almost a dozen a week but since the opening of navigation this year only two cargoes, comprising a total of 10,000 tons of soft coal have been unloaded. Dealers here state that the stocks of hard coal on hand are utterly inadquate to meet demands and that stocks of soft coal will be exhausted by the middle of October. Some hope was held out by Cleveland exporters of shipments of coal mined in non-union mines but since the start of the railroad strike in the United States, carloads have ceased to come forward and storage yards at Cleveland are practically empty. Vessel owners will be forced to tie-up their ships unless a change for the better occurs.

Klompf and Hardy, Fort William, have been awarded the contract for construction of a new oil warehouse for the Canadian Oil company here. The building will cost $4,000.

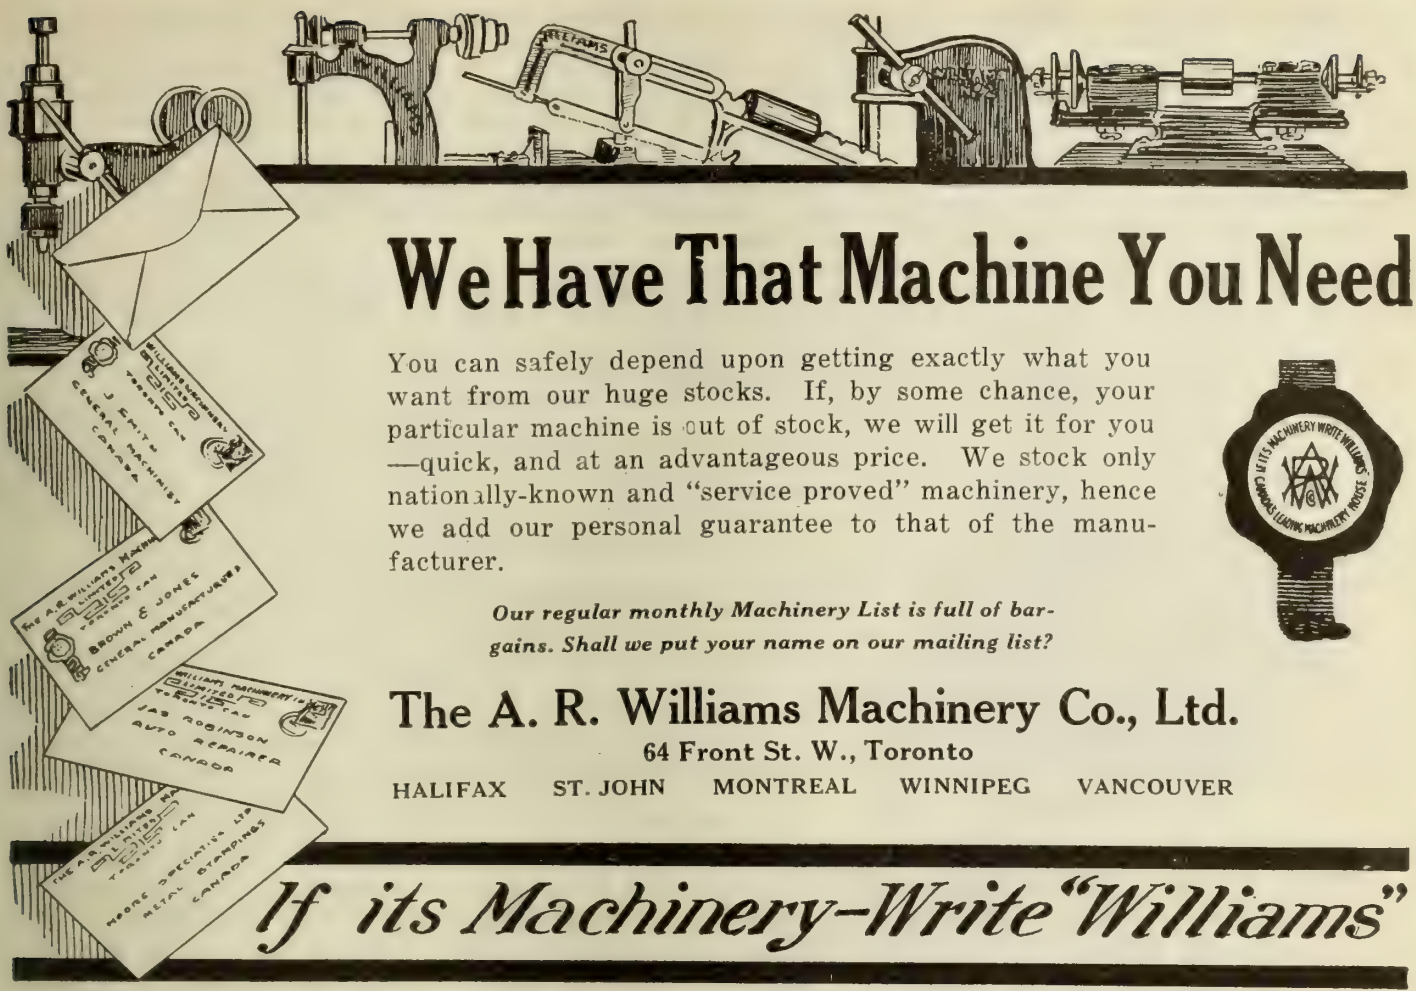
A vacancy will probably occur during the next few weeks in the board of grain commissioners of Canada, due to the resignation of Commissioner J. P. Jones, Fort Willian, whose term of office will expire early next year, but who is likely to have his resignation accepted a few months early in order that he may take a position with a Western grain firm. Word from Ottawa intimates that mention has been made of James Robinson, a director of the Saskatchewan Co-operative Grain company, for the position.

According to plans, the enlargement of the Port Arthur plant of the Consolidated Water Power and Paper company will be proceeded with at once. The capacity of the present pulpmill will be doubled and a one hundred ton daily capacity paper mill will be constructed. The entire plant when completed will use 10,000 horse-power electric energy instead of 1,500 as at present. The name of the Port Arthur plant has been changed to the Thunder Bay Paper mills.

Progress is being made in the construction of the new sorting, transferring and storage yards being established by the Canadian National railways upon two hundred and fifty acres of land just west of the westerly limits of Fort William. The new yards besides containing many miles of tracks will contain a roundhouse and offices. The plant when completed will represent an outlay of over two million dollars of which the sum of $470,000 has been appropriated by the government in this year's estimates. The yard is part of the government objective to co-ordinate the old Canadian Northern and the Grand Trunk Pacific railroads.

A MODEL FACTORY

One of the most admirably equipped factories in the world has recently been erected near London, England, for the manufacture of confectionery and for the packing of tea. In the tea department the whole of the work is done by machinery, the tea not being touched by hand from beginning to end. The tea chests are brought in barges to a canal dock and lifted out of the barges by means of an electric transporter which carries them into the factory. They are then raised by an electric conveyor to an upper floor where a sample is taken for tasting purposes The tea is then emptied down chutes leading to automatic machines which weigh out the tea in pounds, half pounds, or quarter pounds, as required, shape a package out of sheets of paper, fill the package with the exact weight of tea, and then close the packet. This packing operation is done at the rate of one complete package per second. The packages are then made up in parcels of one dozen or more and placed on electric trucks which convey them to the despatch department.



We Have That Machine You Need

You can safely depend upon getting exactly what you want from our huge stocks. If, by some chance, your particular machine is out of stock, we will get it for you —quick, and at an advantageous price. We stock only nationally-known and "service proved" machinery, hence we add our personal guarantee to that of the manufacturer.

Our regular monthly Machinery List is full of bargains. Shall we put your name on our mailing list?

The A. R. Williams Machinery Co., Ltd.

64 Front St. W., Toronto

HALIFAX ST. JOHN MONTREAL WINNIPEG VANCOUVER

If its Machinery—Write "Williams"

STEADY RETURN TO NORMAL

London, Eng.—The outlook in the machinery and engineering trades has, naturally, been very materially improved by the favorable result of the ballot taken by the union on the question of a return to work. Although it may be a question of some time before the industry is once more in full swing, there is now nothing to look forward to other than a steady return towards normal conditions—a prospect which affects not only these allied industries, but a very large section of the country's trades. Order books are, of course, fuller than they would have been had the men been working, but firms are particularly desirous of securing long term contracts. For this, for countries where conditions are stable and risks are small, particularly attractive prices can be quoted. Enquiries have somewhat fallen off again more recently, probably owing to the trade dispute, but the work of regaining pre-war markets, particularly in heavy standard types of machinery, is not likely to receive any serious check from outside.

As to machinery developments, Messrs. H. G. L. Young have recently brought out some small woodworking machines, which should be very suitable where large woodworking machinery is not suitable for the work to be performed. For example, a thicknesser has been designed to meet the needs of woodworkers in a small way of business. Although small and cheap these machines will plane wood up to 6 ins. wide and 4 in. thick. The dimensions are 22⅛ ins. by 19 in. by 14 ins., and its weight is ¾ cwt. The machines can be driven from a ¾ h.p. electric motor or from a counter shaft. A circular saw bench has also been designed in which the table measures 24 ins. by 14 ins. and it is fitted with a 12 in. circular saw. This machine measures only 27 ins. in 19 ins. by 16 ins. and weighs 1¾ cwts. It will run normally at a speed of 1,500 r.p.m., and can be driven by a 1 h.p. motor. Other products of this maker include a bench spindle milling machine and a band saw. All these machines, although quite small, are well designed and efficient.

In welding and cutting, the past few years have seen a great deal of progress in the development, and both the electrical and gaseous methods of welding appear to have established themselves for various types of operation with great success. In one particular field the welding process has been of the utmost value, viz., for repair work on broken or damaged castings, or forgings. Not only have these been repaired with great ease and low cost, but the period of delay, during which the machinery has been out of operation owing to the damage in the first place, has been enormously reduced. As an example of this a recent case was quoted in which a large steamship fractured the three cylinder castings of her triple expansion engine. The cost of replacement would have been £50,000, and it would have been necessary for the ship to be laid up for six months. A firm of welding specialists undertook the repair, and the steamship was returned to service in five days. Lloyd's surveyor subsequently passed her A. 1. It is obvious also that apart from the saving in the delay while the ship was held up for the repair the cost of the welding itself was merely a fraction of that charged for the new cylinders. In this case the total length of the fractures was 14½ feet in metal 3 inches thick.

So much has the oxy-acetylene process developed, that profiling to exceedingly fine limits and with speed as well as accuracy is now quite possible, and is not difficult. At recent exhibitions workmen have been seen demonstrating the process by which a gear wheel has been cut out with the teeth accurately formed to within one-twentieth of an inch, in plate half an inch thick. The time required is merely one-tenth of that necessary by the older machine methods and the subsequent machining operation in the case of a piece of work such as a gear wheel is enormously reduced, owing to the very small amount of material which it is necessary to remove after the blow pipe has done its work.

OXYGEN PRODUCERS CONSOLIDATE

The consolidation recently of the manufacturing and distributing resources of the Dominion Oxygen Company, Limited, and the National Electro Products, Limited, gives to Canada one of the largest organizations of its kind on the continent. The business is henceforth to be conducted under the name of the Dominion Oxygen Company, Limited, now operating oxygen plants at Montreal and Toronto, and acetylene plants at Merriton, Winnipeg and Shawinigan Falls. In addition the company conducts oxygen and acetylene distributing stations at Hamilton, Windsor and Quebec. It is claimed that the union of the two companies will be of material advantage to all Canadian oxygen users through stabilization of the product, assurance of steady supply and certain improvements in service that enlarged facilities will make possible. It is understood that Mr. W. J. Cluff and associates, of Toronto and Montreal, who founded the National Electro Products, Limited, several years ago, will retain their relationship with the oxygen industry through their interest in the consolidated companies.

STRIKES AND BETTER BUSINESS

Delay in reaching settlements of present labor troubles will temporarily delay expansion, but it will not affect the fundamental causes which for more than a year have been making for better business, declares a New York authority on the situation in the United States.

Conditions at the close of the first half of 1922 indicate that business will expand moderately during the autumn and winter months. It is now one year since the definite beginning of recovery from the depression of 1920-1. Progress was slow until the close of 1921, but since the beginning of 1922 improvement has been rapid. Money is cheap. The crop outlook is excellent. With few exceptions, stocks of raw materials and of manufactured products are not larger than necessary to bridge the normal period between production and consumption. Commodity prices are rising. The movement at present seems to be primarily one of adjustment between the different classes of commodities, and as long as the upward tendency does not assume a speculative character, it is a favorable factor. Except for strikes, there is little idleness. Production has expanded steadily since the beginning of the year, and as yet the usual mid-summer dullness has been little felt.

FIGHTING FOR A CONTRACT

In the consideration of tenders for a four million gallon centrifugal pump for the Toronto Island pumping station, Commissioner Harris, before Toronto Board of Control, was disinclined to award the contract to the John Inglis Co., Toronto, claiming that they were not equipped. He seemed to have lost sight of the fact that the Inglis people have installed pumps to the capacity of two hundred millions of gallons in Toronto services. They have put in a tender of $10,791, which, after some show of a fight in the Board, was accepted. The Toronto plants having Inglis equipment are the main station, twenty million gallons, electrically driven; filtration plant, seventy-five million gallons, steam; sewage plant, twenty, seven, and one and one-half million gallons electric; main station, fifteen million gallons. Corliss steam; high level, six million gallons, Corliss steam; filtration plant, two million gallons, duplex steam.

"It's pretty tough when a Toronto man can't get a job in his own city," Mr. Inglis told the Board.

"The other pump is a better pump, that's all," remarked Commissioner Harris.

"That makes it a serious matter when the Toronto firm says it will build a pump according to your specifications and with a guarantee," said the mayor.

"What's the use of calling for tenders?" asked another controller, who moved that the local firm get the contract. The motion was carried four to one.

IMPROVEMENT IN GALT

All indications point to improvement industrially in Galt. While conditions in many branches could be much better, there is a more optimistic feeling among manufacturers generally. It is gratifying to learn that several of the large plants producing iron and steel report an increase in the number of working hours, more hands being taken on and good prospects for the future.

Cowan and Company, Limited, wood working machinery, are now working five and a half days a week and a number of the hands who were laid off during the slack period are back at work again.

Shurly-Dietrich Co., Limited, saw manufacturers, have lately taken on some more men and are working five days a week. Reports from the lumbering districts in the north say that the lumber companies are putting men into the bush now, which is earlier than usual, thus creating a greater demand for saws.

The Canada Machinery Corporation, Limited, wood and iron working machine tools, say business is now on the up grade. More hands are being taken on and the total number of employees at the present time is greater than at any time during the past year. They are now working five and a half days a week.

The R. McDougall Co., Limited, are very busy in their pump department and are working full time.

Conditions at the Galt Stove and Furnace Company, Limited, have been steadily improving since the middle of April. The moulders are now working four days and other employees five and a half days a week.

The Galt Art Metal Co., Limited, are very busy and were it not for the fact that supplies of material are slow in arriving, the factory could be working ten hours a day instead of eight as at present.

The Greenfield Tap and Die Corporation, Limited, the Galt Knife Company, Ltd., both report business as improving.

The Dominion Tack and Nail Co., Limited, are fairly busy and are working full time.

Galt Brass Co., Limited, report "exceptionally busy," and the prospects for future business "very good."

The C. Turnbull Co., Limited, knitted underwear manufacturers, have, through the recent purchase of the oatmeal mill adjoining their factory on North Water street, added another 8,000 feet to their floor space, which is good evidence of progress in their particular line.

Stauffer-Dobbie, Limited, report business good, employees working five and a half days a week.

P. W. Gardiner & Son, sash and door manufacturerss, say business in June, both wholesale and retail, was very good and on account of so much building going on at the present time in large centres, future prospects were bright. The firm is employing a normal number of hands who are working fifty hours a week.

HEATING AND VENTILATING ENGINEERS

A Canadian Chapter has been formed of the American Association of Heating and Ventilating Engineers, to be known as the "Canadian Division, Ontario Chapter," with a membership of about 35. The first meeting was held on June 2nd and the following officers appointed:

M. F. Thomas, president; H. H. Angus, vice-president; A. S. Leitch, secretary; A. J. Dickey, treasurer.

Monthly meetings will be held in Toronto.

RURAL POPULATION LEADS

The final figure issued from Ottawa of the sixth census, as of June 1st, gives Canada a population of 8,788,483, an increase of 1,581,840 over 1911 or 21.95 per cent. The census figures show 4,439,505 of the total population residing in rural districts as compared with 4,348,978 living in urban centres. Ontario is leading the way among the Provinces both as to total population and in the number living in the country. Ontario's total population is 2,933,662, of whom 1,226,292 live in rural districts. Quebec is second with a total population of 2,361,199, of whom 1,038,128 reside in the country.

For recording degrees of heat above those possible of indication by the mercurial thermometer, a pyrometer is used. This registers or measures by means of multiplying levers and a scale, the effect of heat upon some expansive substance such as a metallic rod when exposed to the heat to be measured.

Geometric

Screw Cutting Tools

Do the Work and Stand Up Through Long and Constant Service.

Men long experienced in Screw Thread Cutting affirm they were the losers where they had been induced to try substitutes.

A Geometric Self-Opening Die Head of just the right construction for your work, and a set of Geometric Milled Chasers—

Did you ever try to beat that combination on your Screw Machine or Turret Lathe?

A Geometric Collapsing Tap on your Screw Machine, Turret Lathe or live Spindle will prove if it is not the best possible investment.

Ready To-day--MacLean's Mid-Summer

All Fiction Number

BY WAY of an innovation, the August 1st issue of MACLEAN'S MAGAZINE has been produced as a Mid-Summer All-Fiction Number. The cover is by C. H. Taffs, the noted English artist who made such a hit with the cover of our January 1st issue this year.

There will be the usual Review of Reviews section, the Woman's Department, the Scoutmasters' and the Financial Departments; but, for this one issue, there will be no other serious original articles.

The chief feature of this issue will be a 42,000 word novel,

"THE JADE GOD," by Alan Sullivan

Never before has a complete novel been published in one issue of a Canadian periodical. In fact, there are few magazines in United States which have ever done it. There will be ten full pages of this novel at the front, well illustrated, as well as a generous turnover at the back of the magazine. In book form this one novel would sell for $1.75.

$1.75 Novel — **August 1st** — For Only 20c

Other big fiction features in the August 1st issue include—

"CHEESE," by Henry Holt, is the story of a business man who has spent his life manufacturing cheese —and made a big success of it. He suddenly gives way to an impulse which his wife cannot curb and which leads him through many ventures, New York, Paris, Monte Carlo—in all of which he learns to "take a chance."

"THE PINK PAGODA" is from the pen of Isabel Ecclestone McKay, that charming Canadian novelist who looks out on the world from her comfortable Vancouver home and who has achieved such a recent success with her book, "The Window Gazer."

"THE GUEST OF TRADITION" is a newspaper yarn by J. L. Rutledge. George Wilcox was a tradition around the old "Examiner" office and whenever cub reporters came on the staff they were urged to write like Wilcox. But Wilcox met a dainty little bit of femininity from the stage and the criss-crossing of their lives, and the wrecking of his ambition, are woven into an extraordinarily gripping tale.

"PER AGREEMENT" is by Archie McKishnie and is a mystery story told in this Canadian writer's best vein.

"HOOKS AND EYES," by Lloyd Roberts. Something is bound to happen when a bunch of New York chorus girls decide to venture into the Canadian wilds during the off-season (speaking theatrically), in order to get into condition for the rigors of their winter performances.

"THE TRYST OF THE WHITE LADY," by L. M. Montgomery. This is a delightful little love story with a very unusual turn to it, a story which measures up to the high standard which you expect from the author of "Anne of Green Gables."

"OVINGTON'S BANK," by Stanley J. Weyman. This is the next to the concluding instalment of this most popular serial.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

Deep Groove Ball Bearings on Worm Drives

THE shock of starting heavy loads, the effect of pounding over cobbles or country roads and the steady grind of miles of running are part of the daily work of worm drives.

Every unexpected bump, every impulse of the engine and every sudden stop makes its reaction felt on the bearings. In worm gears the duty of eliminating destructive effects of vibration and keeping every part permanently in place ultimately falls upon the bearings.

SKF marked deep groove bearings have proven particularly suitable to such locations, where radial and thrust loads are subject to continual variations. The bearing can withstand thrust loads in excess of its radial rating, depending on speed and load conditions. This characteristic together with the precision of workmanship and the quality of materials used, furnishes the strength and durability necessary for the most exacting service.

You are urged to make use of our engineering facilities in the solution of your bearing problems.

here it is —

The new Starrett Pistol Grip Adjustable Hacksaw Frame

The frame you would make if you were designing a hack saw for your own personal use. Substantially built and beautifully finished—checked hard rubber handle and stream line design.

This new Hack Saw Frame has several features not found on any other frame on the market. Constant spring tension on the bolts that hold the blade and a positive adjustment on the tubular back, make blade changing a quick and easy operation. Without removing the wing nut, the blade can be set to cut four ways and any length from 8 to 12 inches can be used.

You can appreciate the Starrett Pistol Grip Frame only by seeing and handling it. Any hardware man will be glad to show it to you.

Write for Catalog No. 223 and the Supplement describing the new Starrett Tools.

Vol. XXVIII. No. 5 Published Weekly by the MacLean Publishing Company, Limited, Toronto, Ont. August 3, 1922 $4.00 a Year Subscription Price

READ AND PASS TO	Check	See Page	READ AND PASS TO	Check	See Page

These Are Important Dates

One problem, sometimes clouding the industrial perspective under conditions such as exist to-day is that which has to do with definite objective. There is so much sameness in the average outlook, manufacturers declare, that there is danger of it becoming deceptive.

That is why positive plans have the advantage over negative attitude. They act as a guide to future action. That is why we submit to our advertisers the following list of feature articles and numbers, selected from our program for the next three months. They represent special advertising values calculated to give particular emphasis to your campaign.

Feature Numbers

SEPTEMBER 28—Do It Pneumatically—Describing and illustrating the application of pneumatic tools and other equipment in modern production.
OCTOBER 19—Do It Automatically. This will deal with a large and important field—the automatic tools and machinery in their relation to industrial achievement.

Feature Articles

AUGUST 24—Production Drilling—Examples of Work Performed.
SEPTEMBER 7—The Value of Die Casting to Industry.
OCTOBER 5—Making the Repair Shop PAY Its Way.
OCTOBER 12—Securing Production by Means of the Turret Lathe.
OCTOBER 26—Are You Losing Money on YOUR Benches?

The above articles and numbers, valuable to the manufacturer desiring to develop the interest of his market, will also have their appeal to the man who would post himself upon best developments in engineering and mechanical enterprise. They are selected from a program comprising a wide range of important subjects. They constitute a message of co-operation from

DOMINION OXYGEN SERVICE

BROADER IN SCOPE AND MORE EFFICIENT

THREE years ago Dominion Oxygen service was but a vision. Beginning with one oxygen plant, in Toronto, Dominion Service has expanded until it now owns the largest and most modern oxygen plants in Canada.

In addition, Dominion Oxygen Service includes Prest-O-Lite Gas (Dissolved Acetylene).

Operating both oxygen and Prest-O-Lite Gas Plants and with a chain of Distributing Warehouses at centrally located points, Dominion Oxygen Service offers the purest products obtainable, in any quantity required, shipped in the most modern cylinders, and always delivered on time.

Representing the Leading Manufacturers

In addition to manufacturing and distributing Fairbanks-Morse products, The Canadian Fairbanks-Morse Co., Limited, represents the leading manufacturers of mechanical goods.

When ordering from our nearest branch, you are ordering from the manufacturer whose product has proved itself the acknowledged leader in its particular field. Here are some of the well known lines we handle:—

Fairbanks Valves
Brown & Sharpe Machine Tools
McDougall Lathes
Gisholt Turret Lathes
South Bend Engine Lathes
Landis Threaders
Graton & Knight Leather Belting
Yale Chain Hoists
Esterbrook-Allcard High Speed Drills

There is no royal road to knowledge nor is there a short cut to good workmanship. But in pointing the way to proficiency, good tools are to the workman what good books are to the scholar, and the greater his skill the more particular he is as to what goes into his tool kit. It is significant that two generations of men who work metal within close limits have learned to rely on the never-failing accuracy of Starrett Tools.

Genuine Bitisrh Oak Tanned Belting

YOU cannot afford to use belting that is cheaply made—of poor leather and by slipshod methods. Under-cut prices may appeal—at first, but pretty soon you run into belt-slippage and that's where you start in to add to the first cost.

Every foot of D. K. McLaren's Belting is made from the backs of choicest hides and is subjected to the Genuine **British Oak Tanning Process**. It is this that gives it a toughness, flexibility and gripping power that reduces belt-slippage to a positive minimum.

Carbons for Electric Arc Welding

THE electric welding industry has been tremendously advanced by the high development of arc carbons for specific purposes. We manufacture the following grades, named in the order of their current carrying capacities:—

Plain Welding Carbon:
A hard carbon for Ordinary service.

Columbia Welding Carbon:
Very hard. It can also be furnished copper coated, making it suitable for use as a cutting electrode as well as for heavy welding work.

Special Graphite Welding Carbon:
Rather soft and graphitic. High conductivity. Used where a high amperage is required. Used with excellent results on general work.

Buried in the Work and Broke!

Next time a tap breaks below the surface of a large casting, don't let some makeshift method of removing it injure the thread and waste half an hour of valuable production time. Instead—

Walton it Out in a Jiffy

And save the casting.

Special analysis steel fingers of the Walton Extractor drop into the flutes of the broken tap—and grip. Then a few turns of a wrench applied to the squared end of the Extractor backs out the buried tap.

Sixty-day trial offer proves the Walton Extractor pays for itself. Write.

The Walton Co.
Hartford, Conn.

Shall cleaning room capacity be increased by employing a more efficient cleaning material?

OR?

or—shall capacity be increased by spending more money for equipment and labor?

More work from the same cleaning tanks— or more equipment and more men?

"This Advertisement is one of a series based on actual occurrences."

AS production increases, the cleaning of work in process of manufacture must keep pace. This often results in a condition where it apparently becomes necessary to provide for increased equipment and labor in order to keep up with the growing volume of cleaning work.

But many plants and shops have found that there is another way to solve this problem. They have found that by using Oakite materials and methods they could avoid the expense of extra equipment and would not have to put more men on the job. The reason is that Oakite cleans *faster* than the materials they have been using and cleans with absolute thoroughness.

Write for our booklet "Modern Metal Cleaning"

This fact is well emphasized by the experience of a large electrical equipment plant. Increasing demand for its products created a cleaning problem. Based on the equipment and materials in use it was evident that the capacity of the cleaning room had to be doubled.

The situation was met most satisfactorily, not by spending money for new tank equipment, nor by adding to the payroll, but by using Oakite cleaning materials and by making a few changes in the method of handling the cleaning job. They report they are handling their cleaning work faster and better than they believed was possible, and they are having no trouble in keeping up with the demand.

If you have need for faster, better cleaning we can help you. It incurs no obligation to have a friendly talk with one of our experienced Service Men. Out of his broad experience and ability you are sure to get some useful ideas that are worth while. Drop us a postal card—it is a little thing to do but a big step in the right direction.

Service You Can Depend Upon

OUTPUT lost through breakdowns cannot be made up by spurts of speed. Only by the steady continuous operation of efficient machinery is it possible to maintain the necessary volume of production. Therefore, when you are buying a machine buy one which will give you long, hard, continuous and efficient service.

For half a century "B-B" line has met the approval of particular buyers—it has a reputation for service you can depend upon.

The "B-B" Line

The "B-B" line comprises tinsmiths' tools and sheet metal working machines of all kinds; canners' and evaporators' machinery; shears of every description; power presses for punching, forming, embossing, blanking.

We shall be glad to send you catalogs containing full descriptions of the machines and tools in which you are interested.

Tapping 1,200 Control Rod Clevices Per Day

And doing it regularly WITHOUT BROKEN TAPS is an achievement possible only with the

"Procunier" Safety Tapping Attachment

the only device on the market having a **balanced** reversing mechanism, which eliminates all side pull or torsion.

Its positive grip on the tap gives steady production; automatic reverse as the drill press spindle is raised saves time and prevents damage to tap or work in backing out; reversing at twice the forward speed increases rate of output.

WILLIAM L. PROCUNIER THE PROCUNIER LINE CHICAGO ILL.

Ask us for actual facts and figures as proof that Procunier Tapping Attachments will increase your production without increased costs.

WILLIAM L. PROCUNIER, 18 South Clinton St., CHICAGO, ILL.

HENDEY

You Need It
For Those Particular Jobs

WHEN you are up against a particular job that requires careful machining and the time set for finishing is short, you naturally look about for a machine tool that has an ability record.

Hendey Shapers produce to the closest limits and exert a power behind the tool that appreciably reduces operating time. For keeping the volume and accuracy of your products up and the producing cost down, you need Hendey Shapers.

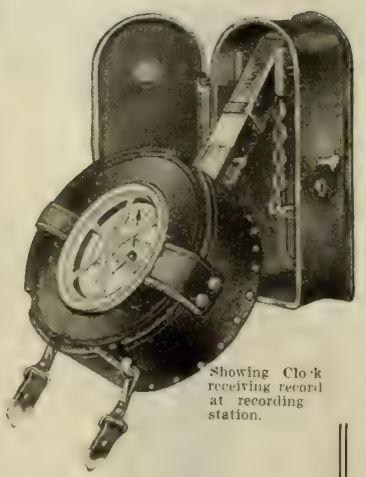
Hendey 20-in. Crank Shaper

Your Watchman Is Only Human



Showing Clock receiving record at recording station.

What proof have you that your watchman is "on the job" all the time? How can you be sure he'll be on hand to notice any small blaze that might occur—one of those small blazes that often mean ruin if not caught in time? He's only human, you know. He may mean to do right but—supposing you **knew** he "slipped a round" once in a while—would you sleep easy?

Sure, you'd get your insurance in case of fire, you might even re-build; but what about loss of production and disorganization in the meantime? Worth a few minutes thought, isn't it?

Let us tell you just how the Hardinge System will **protect** you absolutely. No wiring or other complications, the only tool needed is a screw-driver. It's ridiculously inexpensive too.

This is what we'll do. We will install the system in your plant for 30 days' trial without suggestion or prompting from us. If it doesn't convince you it's something you can't do without, there's no harm done—all the charges are on us. How about it?

Hardinge Bros. of Canada, Ltd.

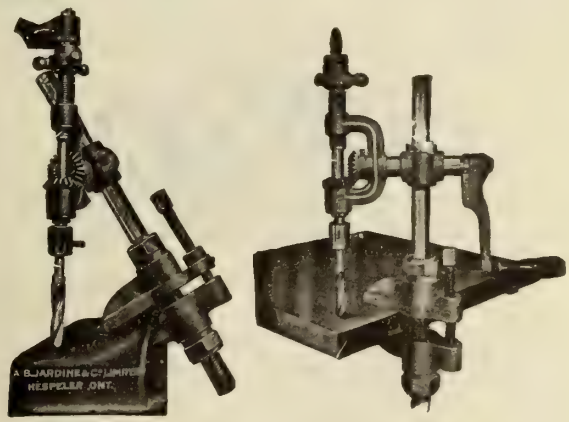
Jardine Universal Ratchet Drill

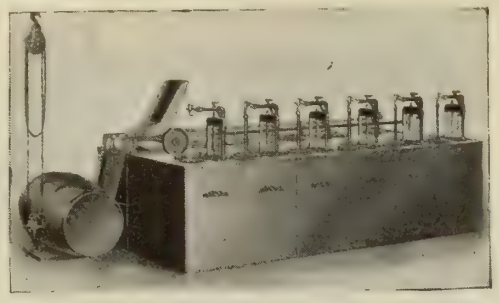
Time is expensive when a machine is standing idle, waiting for repairs.



On the average repair job, this machine completes the drilling in less than the time required to set an ordinary ratchet to begin.

Weight, 40 lbs. Price, $26.50 net.
Sold by all Machinery and Supply Houses.

A. B. JARDINE & CO., Limited
HESPELER, ONTARIO



Save Money and Machinery by Correct Storage

Save labor, be sure of clean oil, eliminate fire hazards—and buy less oil—by using Bowser Piston-Type Measuring Pump for handling oils.

Accurate measurement saves oil; Bowsers are accurate. Oil-tight construction eliminates losses—Bowsers are oil-tight. Spillage means waste—Bowsers prevent spillage. And such a battery of oil tanks as is shown saves hand labor—cuts down operating costs and overhead.

Full details, as to exactly how much money you can save per year, and how soon the Bowser equipment will pay for itself, will be supplied by our engineering division. Ask for illustrated Folder C-13, and state your problem briefly.

1800 Staybolt Holes

THAT is the number of staybolt holes tapped with ONE GTD Maxi Staybolt Tap in a large eastern railroad shop (name on request). This is by no means an unusual Maxitap performance, for due to the uniform quality of material and workmanship which distinguishes GTD products we expect every

GTD Maxi Staybolt Tap

which we sell to do equally well under similar conditions. It is a typical example of GTD service in railroad shops, which is measured not by the number of taps sold but by the number of holes tapped per tap.

Designed and tempered to meet the exacting requirements of railroad repair work, as well as new work, Maxitaps stand up under the worst conditions encountered—the retapping of old sheets through rust, mud and water scale.

Maxitaps thread more holes, do better work and cut tapping cost wherever used—because of special design and heat treatment. One treatment for new, another for repair work. This "personality" is one reason for the "Maxitap's" production records.

The GTD organization is ready to consult with you on your threading and tapping work.

Write to-day for detailed information.

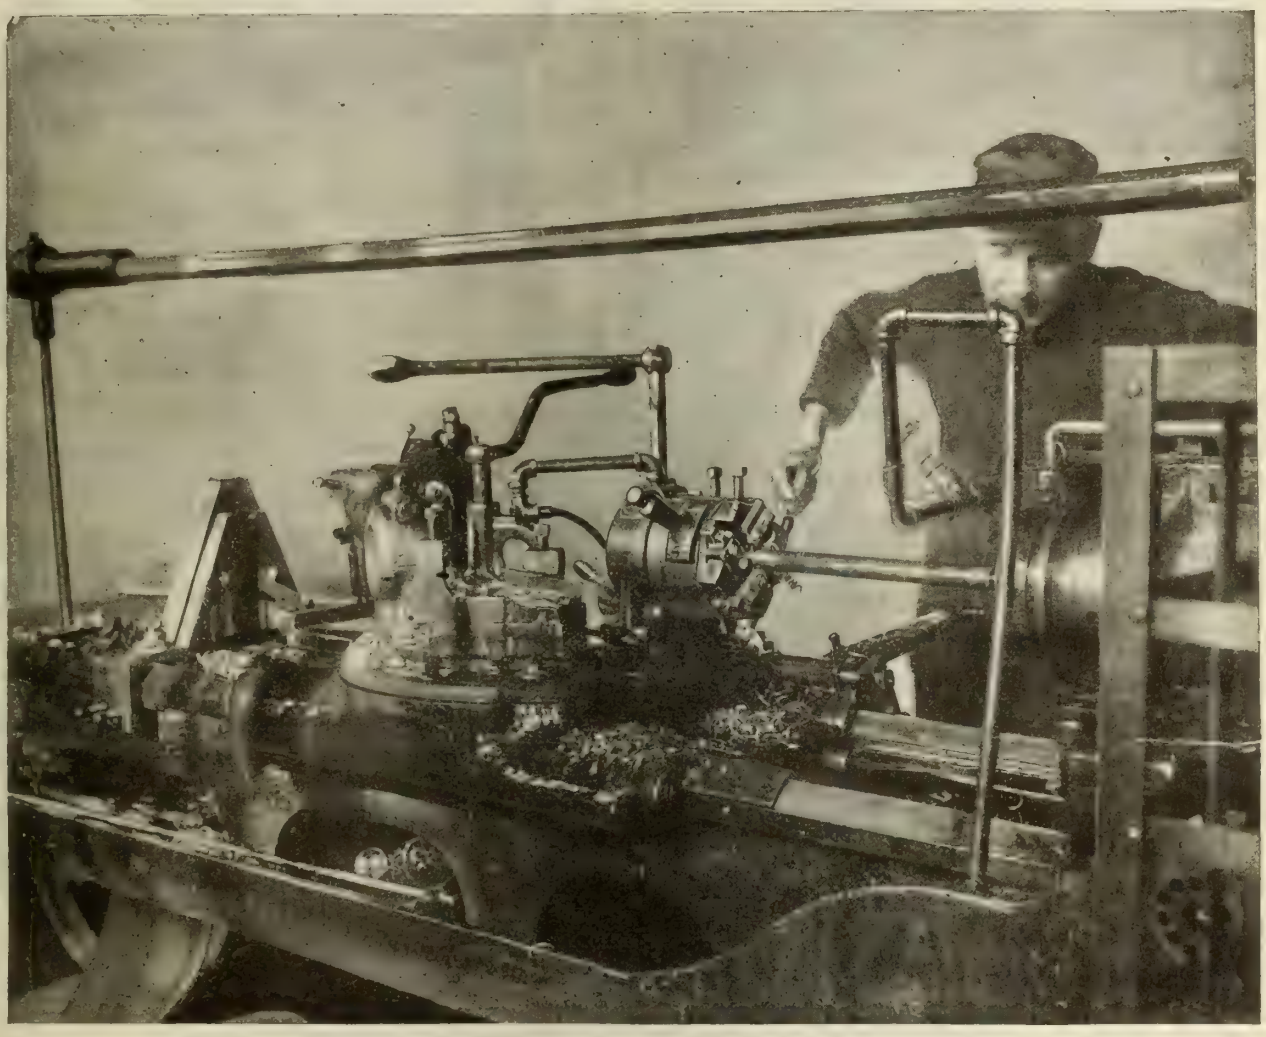
You Take No Risk When You Install the New Type Landis Automatic Die Head



This photograph shows a New Type Landis Automatic Die Head working in a large Canadian plant. Our customer writes: "We are well satisfied with the working of this tool and also the economy in the chasers."

They knew this head would be satisfactory because they have long used the Landis Rotary Head and realized the savings which the Landis Chaser made in their thread cutting.

Landis Automatic Die Heads are similar in design to the rotary type and embody all the features which made the latter a complete success. Furthermore, it employs the Landis chaser, which gives the advantages of the variable cutting angle, the tangential disposition of the chaser to the stock, the interchangeability feature, the simple grinding feature and the fact that annealing, hobbing and retempering are eliminated. These features make for good threads, high production, low chaser cost and dependability.

Would you be interested in trying a New Type Landis Automatic Die Head?

Write at once.

His Safeguard— a PHOTOSTAT Print

Even your most conscientious machinist doesn't have to "make sure" about any figures or lines on a PHOTOSTAT print. He knows that the print was made directly from the original drawing, not from a tracing, and

The PHOTOSTAT makes no mistake. It makes photographic facsimiles.

There is always the possibility of errors in blue prints made from tracings. PHOTOSTAT prints are absolutely accurate.

It takes hours and in some cases even days to make tracings and blue prints. PHOTOSTAT prints are produced in a few minutes.

Tracing takes a skilled draftsman. The operation of a PHOTOSTAT requires only a boy or girl.

Tracings and blue prints cost dollars. PHOTOSTAT prints cost cents.

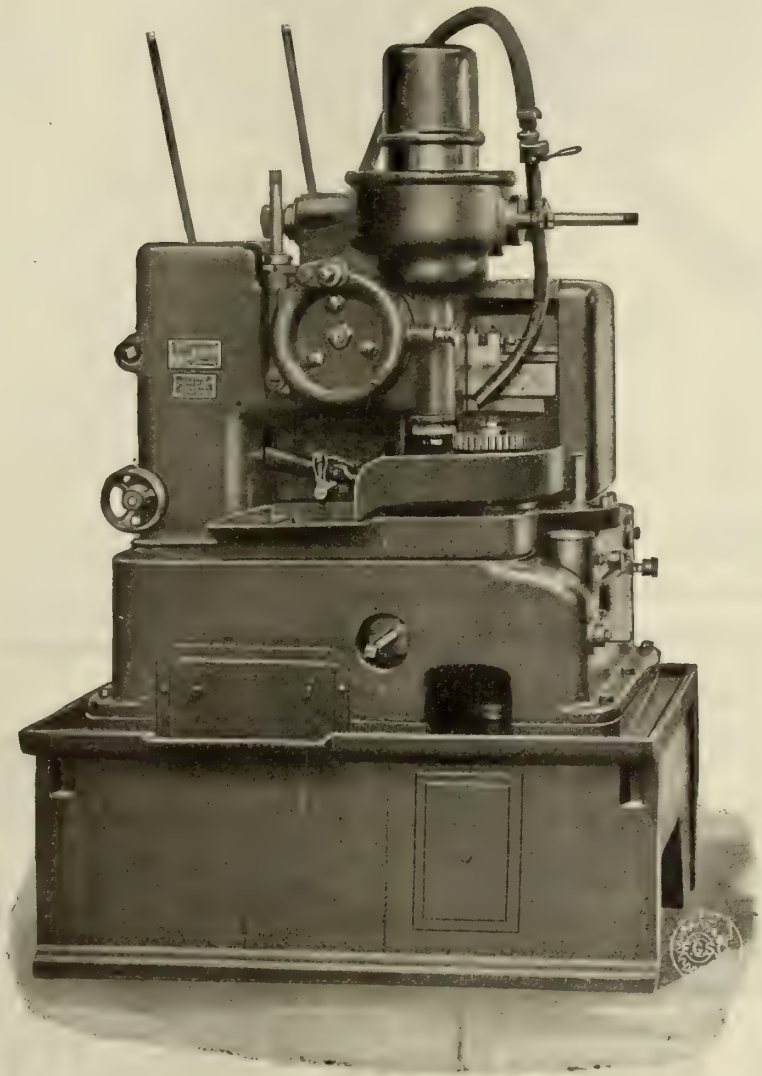
CUT GEAR COSTS
WITH THE
New Production Gear Shaper



The new production Gear Shaper, illustrated, has been designed to cut gear costs. It incorporates every feature necessary in a gear cutting machine to obtain this result, and still one of the outstanding features of the Gear Shaper principle—accuracy—has been maintained.
It is designed to cut one gear at a time and at a speed which eclipses all other methods.
All operating levers are at the front of the machine, permitting a number to be bolted together and operated as a unit, one 6 H.P. motor furnishing ample power for 10 machines
It incorporates to the fullest extent the three principal requirements of production—high speed, accuracy and simplicity of operation.
See illustrated article in all technical magazines
Send for our booklet, "A New Development in Gear Cutting," which has been prepared for the benefit of Engineers and Production Managers interested in the best gear cutting equipment available.

ONE SHEPARD ELECTRIC LIFTABOUT —that's all

Lifting, Carrying, and putting down portable garages may be an unusual job—but it has proved simple and easy for a LIFTABOUT.

SPEED—SAFETY—LOW COST were the requirements of this manufacturer: and they were provided when the LIFTABOUT was installed.

(1) The LIFTABOUT picks up a complete garage section; (2) conveys it on I-Beam track over to edge of one story building; and (4) lowers it safely (5) into waiting truck.

This is but one example of the adaptability of a LIFTABOUT.

It really is a hoist for everybody's load-moving and lifting jobs, and is being used in practically every industry and business.

It has lowered production and distribution costs for hundreds. The same economies are possible for you.

The LIFTABOUT story is told comprehensively in our bulletin. Send for it.

ELECTRIC CRANES & HOISTS

Ready To-day--MacLean's Mid-Summer

All Fiction Number

BY WAY of an innovation, the August 1st issue of MACLEAN'S MAGAZINE has been produced as a Mid-Summer All-Fiction Number. The cover is by C. H. Taffs, the noted English artist who made such a hit with the cover of our January 1st issue this year.

There will be the usual Review of Reviews section, the Woman's Department, the Scoutmasters' and the Financial Departments; but, for this one issue, there will be no other serious original articles.

The chief feature of this issue will be a 42,000 word novel,

"THE JADE GOD," by Alan Sullivan

Never before has a complete novel been published in one issue of a Canadian periodical. In fact, there are few magazines in United States which have ever done it. There will be ten full pages of this novel at the front, well illustrated, as well as a generous turnover at the back of the magazine. In book form this one novel would sell for $1.75.

$1.75 Novel **August 1st** **For Only 20c**

Other big fiction features in the August 1st issue include—

"CHEESE," by Henry Holt, is the story of a business man who has spent his life manufacturing cheese —and made a big success of it. He suddenly gives way to an impulse which his wife cannot curb and which leads him through many ventures, New York, Paris, Monte Carlo—in all of which he learns to "take a chance."

"THE PINK PAGODA" is from the pen of Isabel Ecclestone McKay, that charming Canadian novelist who looks out on the world from her comfortable Vancouver home and who has achieved such a recent success with her book, "The Window Gazer."

"THE GUEST OF TRADITION" is a newspaper yarn by J. L. Rutledge. George Wilcox was a tradition around the old "Examiner" office and whenever cub reporters came on the staff they were urged to write like Wilcox. But Wilcox met a dainty little bit of femininity from the stage and the criss-crossing of their lives, and the wrecking of his ambition, are woven into an extraordinarily gripping tale.

"PER AGREEMENT" is by Archie McKishnie and is a mystery story told in this Canadian writer's best vein.

"HOOKS AND EYES," by Lloyd Roberts. Something is bound to happen when a bunch of New York chorus girls decide to venture into the Canadian wilds during the off-season (speaking theatrically), in order to get into condition for the rigors of their winter performances.

"THE TRYST OF THE WHITE LADY," by L. M. Montgomery. This is a delightful little love story with a very unusual turn to it, a story which measures up to the high standard which you expect from the author of "Anne of Green Gables."

"OVINGTON'S BANK," by Stanley J. Weyman. This is the next to the concluding instalment of this most popular serial.

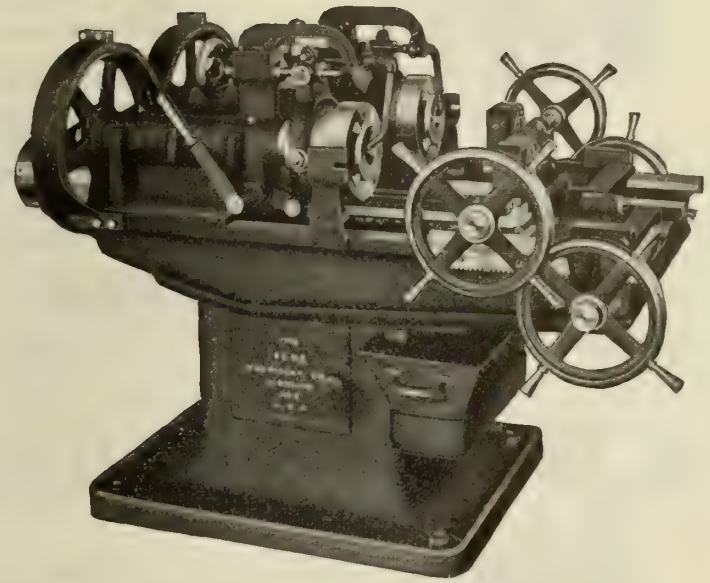
What Are Your Bolts Costing You?



Acme 1½ Inch Double Bolt Cutter--Class A

For Threading and Tapping ⅜ to 1½ inch, either right or left hand. Furnished with motor drive for either direct or alternating current.

IF YOU have never stopped to consider this item of costs it will pay you to do so, particularly if you are buying the bolts you need.

The "ACME" line of Bolt Cutters were designed to meet the demand for cheaper bolt production. That they are now considered standard equipment in progressive shops in all parts of the country is due to the fact that they produce clean, accurate and highly finished threads at a speed that spells certain economy.

All "ACME" Bolt Cutters are equipped with our latest improved micrometer die adjustment, located above the die head within easy reach of the operator, by which means the dies can be finely adjusted to size even while the machine is in motion. Die Heads are automatically opened and closed by the forward and backward motion of the carriages. The Vise Hand Lever is adjustable on the vise screw for all diameters of bolts.

All these features facilitate the rapid feeding of the machine and are particularly appreciated when the pieces are small and speed essential.

Our catalogue gives complete details of "ACME" Bolt, Nut, Rivet, Upsetting and Forging Machinery. Write for a copy.

Pay Us a Visit During Exhibition Week

Here's a real chance to examine that new tool

While in Toronto for the Canadian National Exhibition you are cordially invited to visit us, not only at our booth at the Exhibition but at our Headquarters where we have 130,000 feet of floor space devoted entirely to machinery of all kinds —an exhibition in itself. You are sure to see many machines that will be of special interest to you.

Our headquarters and one warehouse is right next door to Union Station. Our other warehouse is at 27 Bathurst Street; cars for the eastern Exhibition entrance pass the doors.

Here are a few facts

which every one should know who buys Machinery and Supplies.

In our Toronto warehouse we have over 130,000 feet of floor space filled to capacity with machine tools and supplies of every description required in machine shops. Our lines include the best makes on the market. From our immense stock we are always able to meet requirements and our splendid shipping facilities enable us to fill all orders promptly. Our experience extends over half a century. You can always depend upon securing satisfaction when you order from us. Get in the habit of ordering from PETRIE — it pays.

TRAFFIC

a science in itself

Only the institution operating on a major scale can maintain that type of fully-manned, thoroughly-experienced Traffic Department which best guards a buyer from shipping delays, needless freight charges and interruption of production-schedules. It is more than a man-sized responsibility—it is an organization-sized job for a specialized staff such as M. A. Hanna & Co. maintain at all times.

About That "Hurry-Up" Job

YOU KNOW that, in any shop, occasions often arise when "crowding" becomes an absolute necessity —whatever happens, the job must be done on time. Often, the result is quickly dulled cutting edges, poor work and wasted time, for—"haste makes waste."

These are occasions, however, when the reserve strength of Butterfield Tools is properly appreciated. It is because they "stand up on the job"—the "rush job," and permit haste without waste that they have become universally known as "The Tools You Buy Again."

"The Tools You Buy Again"

Why 38 Alundum Grinding Wheels In the Toolroom?

Here are the reasons:

Machine Operator: "I am alright when you send me those red wheels for my Universal Tool and Cutter Grinder."

Tool Room Foreman: "We will use your red wheels now exclusively; they are giving us fine results.

Shop Superintendent: "Those wheels you call 38 Alundum, which we have been getting lately for tools—they're the best we ever had. They cut fast, leave a fine finish and they **do** stand up. And the tools last longer for each sharpening."

Purchasing Agent: "They are still asking for 38 Alundum Wheels out there in the Tool Room, so that's what we will specify on our orders."

For high speed steel tools, or fine sharpening of hardened carbon steel tools, or for surface grinding hardened or high speed steel surfaces, 38 Alundum wheels are particularly adapted.

If you have not tried them, write for full information.

Efficiency Secured by Proper Hoisting Equipment

Methods of Handling Material, and in Smooth Routing of Work, Figure in Industrial Economy—Description of Modern Facilities That Are Paying Their Way and Are Essential Under Competitive Conditions

ECONOMY in present day production hinges largely on the methods of handling the material rather than on the practice adopted in the actual machining of the work. This is especially true as regards engineering works where the operations of making the parts vary but little in many plants. The rapidity of moving the material to and from machines, stock rooms and different departments, is the factor that governs the value of the ultimate result of a multiplicity of conditions.

The demand in recent years for a better system of handling rapidly and economically all classes of material in and about manufacturing plants—both large and small—is becoming more and more insistent. Competition is so keen that it is becoming increasingly difficult to make a profitable showing and still retain the old fashioned hand operated equipment that the other fellow has discarded. The high labor cost makes it almost imperative for the manufacturer to adopt every means of facilitating production by mechanical means. The conservation of human energy is also an important point in deciding whether it is advisable to install better hoisting and conveying equipment. If a man's effort is expended in lifting a heavy casting or pushing a truck load of material, he cannot use it to the best advantage in other and more essential work.

Equipment for Fuel Handling

In every large manufacturing or office building, where the boiler room is below grade level, and where coal is used for fuel, the removal of ashes is a daily hoisting problem. The wheel-barrow method of handling this class of refuse is fast becoming obsolete, the modern practice being to remove the ashes by the means of hoisting equipment. An interesting and economical device for this purpose is shown in Fig. 1. With this appliance it is an easy matter for two men to take care of the entire work of a large establishment with a small amount of effort. The electrically operated hoists will raise loaded cans at a speed of 60 ft. per min., from the boiler room to a point high enough to be discharged directly into a box truck.

The normal position of the hoist when not in use is just below the sidewalk doors, which lie flush with the grade. A condensation gutter, tapped for plumber's drain pipe, which is connected to the sewer, insures a dry area. The first act of the operator is to turn the telescoping handle, which raises head into working position, automatically opening the doors, ringing a four inch electric warning gong for pedestrians on the sidewalk and bringing the guard gates into proper position, so as to protect persons from the dangers of an open hoistway.

Tests for current consumption have shown that at an installation when the boiler room is 12 feet below grade, 78 filled cans of ashes were raised to wagon height and the empties returned to the boiler room, consuming only 1 K.W.H. of electricity. At that plant the cost is $ .03 per K.W.H., which means that 26 cans are raised and lowered for 1 cent. The average time consumed in 1 round trip was 30 seconds. The basic principle of construction naturally divides the hoisting heads into two classes, one of which raises cans to grade level, the other raises can high enough that the ashes may be emptied directly into the cart without rehandling at street level.

For use in buildings where it is not possible for a truck to drive alongside of the opening a type is provided which raises the load to grade level electrically at a speed of 60 feet a minute and lowers by gravity as fast as one can drop a stone. This type of hoist is shown in Fig. 2. In one of the principal buildings of the Bell Telephone System, where the boiler room is 16 feet 8 inches below grade, 296 cans of ashes were raised and the empties lowered using only 1 K.W.

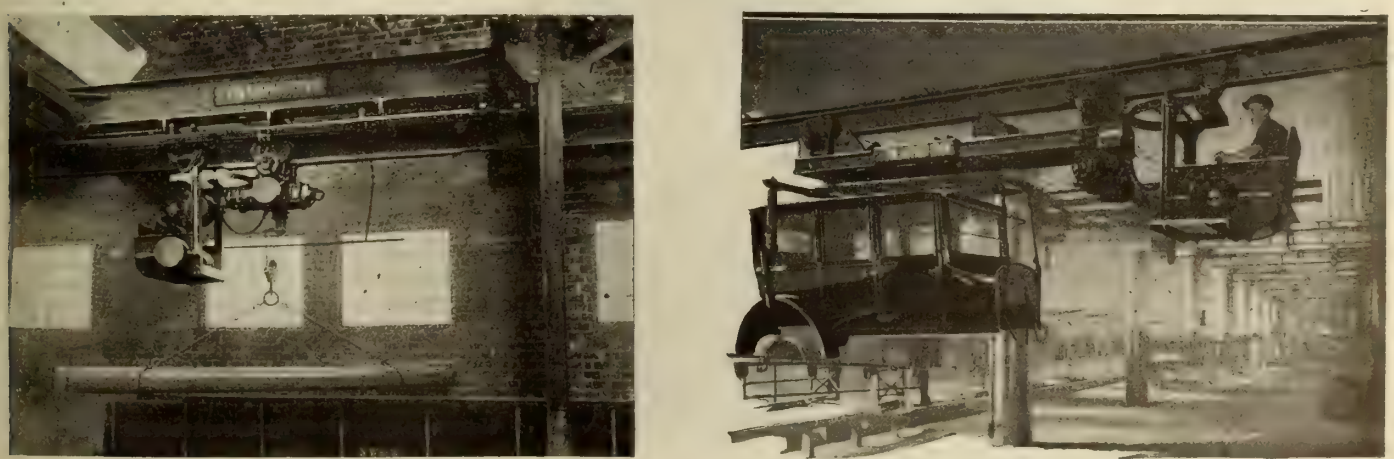

Fig. 4.—On left, hoist handling steel bars. On right, transferring a car body. Overhead track is used here and conveyor has wide range of utility.

H. of current. At the cost of $ .0348 per K.W.H., 85 cans are raised and lowered for 1 cent. The average time raising was 12 seconds, for lowering 1 second.

Pneumatic Hoists

Where compressed air is used in the plant the installation of small direct lift pneumatic hoists provides a convenient

Fig. 3.—Pneumatic motor hoist.

means of handling material around machines. This type of crane is largely used in manufacturing shops for lifting loads from trucks to machines, jib cranes often being provided to serve several tools within its radius.

A pneumatic motor hoist is shown in Fig. 3. These are equipped with a large and powerful worm gear drive. The worm is cut to a pitch that insures locking of the drum and holds the load at any point, even when air is turned off, or when the air line breaks. A particular feature of this type of air hoist is the fact that the load can be raised, and the air line disconnected, after which the trolley may be run to a distant department, another line connected and the load lowered to the desired location.

The throttle valve of the motor has a graduated opening, making it easy to control the speed of the motor and start and stop it gradually. The cylinders are double-acting, placed at right angles and use a single-throw balanced crank shaft, which is connected with the worm.

Great Saving of Floor Space

One of the advantages of the overhead conveying system is the great saving of floor space that is effected and the possibility of piling material to considerable height. Many types of cranes are now in use, each especially adapted to different needs. A hoist that is particularly well suited where material is transferred over a wide area is illustrated in Fig. 4.

The view at the left shows the hoist handling a load of long bars in a large warehouse. The illustration on the right was taken in an automobile plant and shows a hoist with extension arm lifting and transferring the body of a car. A system of overhead track enables a load to be picked up at one end of the plant, convey it to the other—transport it from one building to another—carry it indoors or out—send it any place—without change. It is possible to make it as flexible as a switch engine.

These hoists are employed by many large plants for rehandling coal. Overhead rails are erected over the car tracks and storage piles, carrying hoists with automatic buckets which unload cars and store coal.

This type of combination crane and conveyor can be made a highly efficient and economical means of rapid, interdepartment transportation for any business or industry.

Makes for Efficiency

There are many types of cranes and conveyors in use, from the useful portable floor crane, to the high-tonnage travelling conveyors used in large manufacturing plants. Pneumatic and electrical equipment has been brought to a high state of efficiency and its value in the general scheme of things may be calculated to a nicety. A pneumatic cylinder hoist may be used portably by being suspended from an I-beam trolley running on an overhead rail or it may be mounted in a fixed position. The cost of operation will figure considerably under 1-1000 of a cent per foot of lift per hundred pounds. Another instance of economical operation may be cited in the portable floor hoist. In handling work the overhead crane cannot reach,

Fig. 1.—No rehandling of cans at the grade with this hoist.

this is a useful piece of equipment. Picture five men straining to lift by hand a piece of work which such a machine could handle in a few minutes—meaning, probably, four machines standing idle and thus forty minutes spent on a ten-minute job. Such facilities enable each man to handle his own work with-

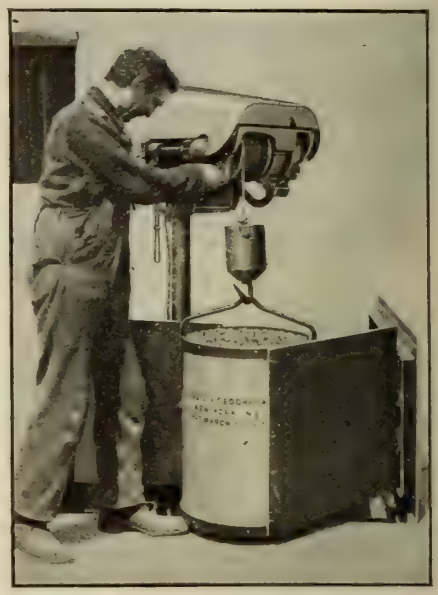

Fig. 2.—With this telescopic hoist one man can raise cans to the grade level faster than two others can empty them into the wagon.

out calling others from their jobs to assist. Each machine is kept at production and heavy work is handled more easily and quickly.

Any consideration of hoisting or conveying equipment must not overlook the importance of the elevator. Installations of this kind have been brought to a high degree of efficiency, and for transferring heavy loads from floor to floor in any scheme of routing the industrial or freight elevator, as it is called, is practically indispensable. It figures in plant economies to such an extent that it is difficult to conceive a plant of any dimensions trying to compete under modern conditions without one. Still, cases are known where industries of some proportions are struggling along in four or five storey buildings without hoisting equipment of any kind. These may be regarded, not as examples of rigid economy, but as exceptions, proving the absolute force of the rule that modern time and labor saving equipment contribute largely to efficiency in capital employed, in time, labor and the competitive power of the product.

Reports that anthracite coal had been discovered near Sudbury are not regarded seriously by the Department of Mines, Toronto. The mineral may be found to be anthraxolite, similar in appearance to anthracite, but of brighter lustre and of lower specific gravity. When it occurs without admixture, it makes a good fuel; but ordinarily it is found mixed with quartz and calcite. In the pure form it has not been found in Canada in commercial quantities.

Careful Handling of Materials Will Show a Profit

Methods Adopted Differ According to Nature of Product—Minimizing Labor Cost—Conveyors Facilitate Inter-Department Transportation—Progressive Routing of Material Aids Production

AT A RECENT meeting of the Worcester Chapter, American Society of Mechanical Engineers held about a month ago, many interesting points were discussed relating to the handling of stock and materials in manufacturing plants. E. C. Evans, of the Wyman-Gordon Co., in speaking on the question, stated that prior to 1915 no serious thought had been given to the handling of goods on a modern efficient basis. The company had no separate heat treating department. The furnaces were set up wherever there might be an available space, and the runways, such as they were, were of dirt, which at places was 3 to 4 in. thick.

Prior to that year the routing was as follows: After the bars of steel were cut to length at the bar shear, they were placed on steel trucks and pulled by four or five men through the dirt of the forge shop to the heat furnaces. The trucks were then unloaded, one bar at a time, and the material placed on the charging table. The bars varied in weight from 30 to 90 lb. each. After a truck was unloaded it was pulled back to the shear and reloaded. The labor turnover on this class of work was great, for two or three days was about as long as a new man would stay on the job.

After the steel was forged, the forgings were thrown on the ground, which required their being picked up again and placed on trucks to be moved to the next department. As no one man was in charge of the routing of material, there resulted a piling up of work around some machines, which greatly hampered efficient operation and reduced production in some departments, caused by waiting for material in process.

Congestion Forces Reforms

In the summer of 1915, with orders piling up on the books, it became apparent that a radical step must be taken to relieve congestion and to rout material properly in the various stages of progress. After investigation it was apparent the problem did not involve traffic alone; with the old arrangement of departments, progressive routing of material was impossible. A new building resulted. All heat treating furnaces were placed in this building, independent of the forge shop. It was then possible to route material in orderly sequence, as follows:

Bar steel is cut to length at the stock yard shear and placed on steel racks. Storage battery trucks move the loaded racks to the forging furnaces, where they are used as charging tables.

From the hammers, all forgings are placed directly on a steel rack, which is carried by an electric truck to the heat treating department. Here all forgings are taken from the racks, when charging the furnaces, and again placed on the racks after they have been heat treated. From the heat treating department, the forgings are taken to the balancing and centering department, then through the pickling room into the inspection and shipping departments.

In the cycle of process, nowhere are the forgings allowed to be thrown on the ground. The principal features of our system for progressive and economical handling of material are nine elevating platform trucks, two charging panels, and 400 specially designed steel racks. No material is allowed to be piled anywhere other than on these racks. One man, in charge of the trucks and operators, is held responsible both for the truck activities and for the maintenance of the equipment. It is a very poor investment to use cheap labor for operators.

Aisleways, of concrete, are kept clear at all times. In the different departments spaces are provided where rack loads of material can be stored ahead of operations. In the finishing, inspection and shipping departments hand operated trucks with elevating platforms are used, to move the racks from one machine to another. All equipment requires instant and efficient attention. Repairs to the equipment should be done in one department and one man be held responsible. All machinists are not expert truck or crane repairmen. All hand trucks which carry loads of a ton or more should be equipped with roller-bearing wheels. A company owes this much to its workmen. Too much thought cannot be given to the purchasing or building of equipment for intra-department transportation, whether it be cranes, trucks or conveyors of any type.

Handling of Gas Coal

Our large forging furnaces are fired with gas coal and over each furnace is mounted a waste-heat boiler. In the yard the coal is dumped by means of a motor driven loader into steel buggies, which hold about one ton, have hinged sides, are mounted on roller-bearing wheels, and are drawn into the shop by a horse. The buggies serve as a coal bin at the furnace, the coal being shoveled from the buggy directly into the fire box. As soon as one buggy is emptied another is rolled into place, and by this method minimum space is used for the storage of coal within the shop.

In conclusion, the industrial executive usually knows how much per piece it costs to produce a given article, but rarely knows what it costs per unit to handle the materials entering into the manufacture of the article, or the cost of handling the finished article. As a usual thing, indirect or non-productive labor is charged to factory burden. A very large percentage of this labor is used in picking up and transporting material.

Any engineer wanting a good talking point in presenting to his management a new system of transportation should separate his old transportation costs from the general factory burden. Too much thought and time cannot be given to the selection of equipment that not only will show a saving, but fits into the general operating conditions of the plant, and, at the same time, permits future extension and development.

Function of a Factory

C. J. Simeon's paper read, in part, as follows:

The function of a factory is to convert materials from one condition to some other condition, which usually includes the assembling of two or more pieces together. In order that these various operations can be performed, the raw or semi-finished material must be handled and stored during the various stages. This introduces a problem which requires a different solution in every plant (or at least in every industry), as it is mainly dependent on the kinds of materials used, and to a less extent on local conditions. The two extremes of this problem are illustrated by a mill producing a bulk product and a jobbing shop.

Differences in Character of Output

In the case of a mill producing material in bulk, such as a flour or steel mill, the work is of such a repetitive nature that it pays to use highly specialized equipment for handling the material in process. As a result, a large proportion of the total equipment is merely for moving and storing the material and, as a matter of fact, in both of these industries the material is not touched by the hand of the man during the entire manufacturing process.

In a jobbing shop the reverse is found. In this case it is seldom that two jobs are exactly alike, although similar jobs may follow each other with

varying frequency. It obviously, therefore, would not pay to spend much money in special handling equipment, and we find even the most up-to-date plants, that are engaged in work of an irregular or special nature, are almost without any special equipment for handling their material. On the other hand, and for the same reasons, such plants require a more highly developed system for keeping track of materials, both in process and storage.

The Morgan Construction Co. more nearly approximates the second than the first example given above. The product is entirely custom-made, designed to order and consequently is very diverse in character and limited in quantity of any kind of article at a time. For this reason the equipment for handling and storing material is of the simplest and most general kind.

Since the nature of the work prevents us from using conveyors to move material from one operation to another, it follows that every move must be made individually. This introduces the danger of a congestion or shortage of material at any one of perhaps several hundred points, unless each move is carefully planned and followed up. The manufacturing portion of the shop is divided as follows:

(a) Ground floor, consisting of bays 1 to 7, all approximately at street level. This contains the heavy machines and main assembling department.

(b) Bays 8 to 10, a few feet above the main shop level, contain machines and light assembling.

(c) The small machine and blacksmith departments are on the second floor, although not over either (a) or (b).

(d) The store room for finished small manufactured and purchased parts is located at the ground floor level, under (c)).

All materials entering the plant are moved as follows, in every case a record of their disposition being sent to the shop office:

(a) If stores or purchased parts, they are taken to the finished store room.

(b) If small castings or forgings, they are placed in the casting storage.

(c) If castings or forgings of large size, requiring a crane to handle a single piece, they are stored under one of the crane runways in Bay 3, 4 or 5, on the right side of the main gangway.

In the shop office are the production records and planning board, from which all movements of material within the factory are controlled. When the planning board finds that certain material will shortly be required to feed a given machine, a "move ticket" is made out and handed to the "move man," giving him particulars of the material and its present location, together with its destination. After making the desired move, this man signs the ticket and returns it to the planning board. The same process is repeated after each operation, until the completed work is finnaly delivered to the store room, if small in size, and to the assembly floor, if too large to be accommodated in the store room.

Owing to the diverse nature of our product, orderly methods of handling material are of greater importance than special equipment. We have practically no special equipment, in the sense of appliances intended to handle some particular piece in quantities, as for example: conveyors, elevators or special trucks. On the other hand, we are unusually well equipped with implements which because of their simplicity, are well adapted to handling material which shows great variety in size, shape and weight. Every one of the ten bays has one, two or three overhead electric cranes. These, together with ordinary rope or chain slings and a few hand trucks, represent about all our handling equipment on the main floor. On the second floor, where the work is all rather small, there are a few light hand cranes, a few tote boxes and lifting platform trucks.

BUSINESS CONDITIONS SHOW IMPROVEMENT

SPEAKING on the industrial outlook in Western Canada, John Sweting, industrial agent of the Canadian Pacific Railway at Winnipeg, says: "Better business has to-day become a fact. During the last few months there has been a gradually growing feeling that the period was arriving when some dependency might be had in price levels, and while there are yet some deflations in rents, wages and fuel, the majority of articles may show a slightly upward movement before a definite level is reached. It may be assumed, however, that trading can be carried on at prices now existing without any great fear of a sufficiently great variation to cause further economic disturbance.

"We have emerged from a period of considerable anxiety with better results than at one time anticipated, and can now promise a very considerable volume of business for the year which will in itself create the foundation for some years of active development and prosperity.

"Perhaps one of the most striking features is the development in building operations. A few weeks ago the outlook was not promising and it seemed to stabilize wages and cost; there is now a very distinct change and while individual buildings of hundred thousand dollars or more class are likely to be small in number, there will be many thousands of smaller buildings, residences, stores, barns, etc., erected throughout the west.

"One noticeable fact is the number of buildings being, and to be, erected in country villages and towns. Every point has its quota, in addition to which farmers are erecting new barns, silos and making other improvements, some of which have undoubtedly been held up pending a return of what may be classified as normal times. While the actual cash value of buildings erected and required for immediate use will, in the aggregate, run into a considerable figure, it is not likely, so far as can be seen at present, that any construction work of magnitude will take place.

EXTEND OPERATIONS IN WESTERN CANADA

MONTREAL.—Thomas McMillan, president Can. Fairbanks-Morse Co. Ltd., recently returned from western Canada, having made an inspection tour of the company's western branches. The agricultural outlook in the west is excellent, and as this factor is more essentially the barometer of conditions in that country than anywhere else, Mr. McMillan feels that prospects for improved general conditions are good, and that his firm will participate in the better trend of matters.

Already his firm has experienced better business in the Maritimes and in the province of Ontario. The latter improvement was due largely to the prosperity of the automotive industry. Better business conditions originated in the east, and moved westward. The large manufacturing firms in Montreal and vicinity were somewhat slower to get under way than the smaller plants in Ontario. For that reason, his firm was getting, at the moment, more business in Ontario. Another factor that handicapped, for the time being, business in Montreal, was the fact that the railways were keeping out of the market.

Mr. McMillan believes that by the time the western crops are harvested, business will have greatly improved. The western farmer, of late, has not been so free to gamble on the future and now waits until his crop is harvested before he goes into the market for his requirements. His company have planned to extend to a considerable extent, their operations in the West. The rate at which these plans of extension will be consummated would, of course, depend upon general conditions, but the expansion would be carried out just as fast as the demands of the country required.

Although confident that the worst of the depression has been passed, Mr. McMillan does not feel that there will be any spectacular recovery overnight, or that the volume of business enjoyed in the war years will be reached for a decade, at least.

The American associate company report business very good, and improving every week, and as these reports originate from offices located in all of the larger centres of the States, they truly reflect conditions across the border. This situation is bound to show itself in Canada from ninety to one hundred days later, according to Mr. McMillan's opinion which is based on many years close observance.

Varied Practice of Producing Gear Teeth Profiles

Defining the Base Circle—Helical Cutting Controlled By Suitable Guides—Hobbing of Gears and Worms—Tangential Feed of Hob—Minimizing Effect of Hob Warpage

By CHESTER B. HAMILTON, JR., B.A.Sc., M.E.

THE following is the continuation of the treatise on gear cutting that has been running for some months past; the last article appeared in the June 1st issue.

Moulding Practice

The Moulding Generating process is the main and might well be the only generating process. That is the gear industry, of this continent at least, would not notice the omission of the Odontograph and describing generating processes. The principle of this process, as well as the methods of production, depend on the fact that the pure involute system of gear teeth is a theoretically correct interchangeable system so far as the tooth curves are concerned. If the length of the teeth is not carried to excess to cause interference, any involute gear will run with any other involute gear of the same pitch, of any number of teeth. This holds true up to the rack, which is a gear of infinite radius, and also equally true for a spur meshing with an internal gear, which may be considered as beyond the rack, being a gear of negative radius, the teeth turning inwards.

Methods of cutting involute teeth by the moulding generating process consist in principle in replacing one number of a pair with a cutting tool which has the same cross section as the gear or rack it replaces. Its edges will then mesh with the second gear, and if this second gear be now replaced by a blank, the tool will cut its teeth in identically the same way. This process is adapted to practically all kinds of gears, spurs, bevels, helicals and worm wheels being correctly produced, though of course with different tools and machines. The Fellows' gear shaper system for spurs and helicals with shafts parallel, uses a cutter which resembles a pinion, that is, its cutting edges are involute curves. This cutter is itself made by the moulding generating process, its edges being ground after hardening by rolling in a constraining mechanism so that it meshes with an emery wheel. The edge of the emery wheel is shaped and located so that it corresponds to the edge of one tooth of an imaginary rack supposed to mesh with the cutter as it rolls. Said in another way—the grinding face of the wheel is straight and lies at an angle equal the pressure angle to the path or tangent on which the base circle of the cutter rolls. In the actual machine the straight grinding face is maintained by frequently dressing with a diamond mounted in a straight slide of suitable angle.

The Base Circle

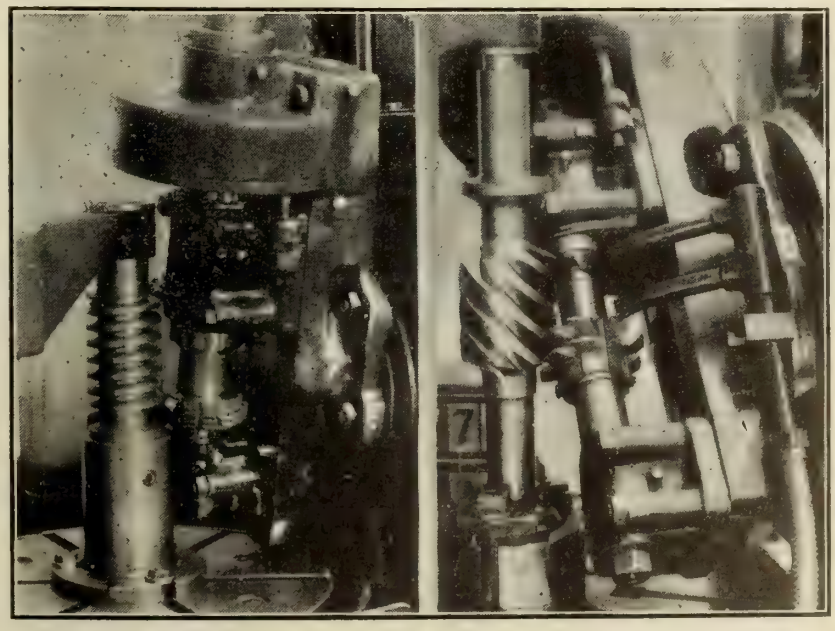
To define the base circle of the cutter, an accurate cylindrical drum is filed adjacent to, and revolving with the cutter, rolling on a straight plane surface, and prevented from slipping or having any other motion than pure rolling by a pair of steel tapes. One of these unrolls as the other rolls up, and they constitute in fact the unwrapping tangents of the theory of the involute. The Fellows cutters are made with teeth parallel the axis for cutting spur gears, and with teeth at an angle for helical and double helical. In the gear cutting machine the cutter is mounted at the lower end of a vertical shaper ram, and reciprocated to plane out the teeth. The cutter on its arbor within the ram is revolved by trains of change gears in ratio with the gear being cut, which is mounted horizontally. In starting to cut the gear the cutter is first fed radially into the work to the desired depth, and then at constant depth revolved in mesh till the work has made one complete revolution. The gear is then complete unless a finish cut is to be taken in a second revolution, in which case the cutter was not fed to full depth the first time, by uually five one-thousandths of an inch.

In the case of helicals the shaper ram is provided with angling guides which give it a partially revolving motion and return, as it reciprocates up and down, this angle corresponding to the angle of the teeth of the helical cutter. The motion is independent of the slowly continuous revolution of the generating motion. Both the spur and helical machines can cut internals, and the helical machine is of course arranged to work on both right and left hand angles. The standard angles of helix are fifteen and twenty-three degrees reckoned from the axis.

It may be mentioned in passing, as a sidelight on the generating process, that a machine working on this process can cut cams and a great variety of peculiar shapes, both internal and external, by using a cutter which was itself generated from a master tool, a duplicate of the work to be produced.

Rack Shape Cutters

Practically all other systems of gear tooth generation use the rack as their basis. In the case of bevel gear generators the rack is in circular form, that is, it is a flat crown gear of 90 degrees pitch angle. The Gleason and Bilgram machines both work on this principle. The Gleason generator for straight tooth gears has two tools working alternately on the two sides of the tooth being cut. Their cutting edges represent the two sides of a tooth space in an imaginary crown gear which would mesh with the gear being cut, when controlled by an actual crown gear which is part of the



Method of generating teeth

Author is President of the Hamilton Gear and Machine Co., and a member of the American Society Mechanical Engineers; Engineering Institute of Canada; Society of Automotive Engineers; American Gear Manufacturers' Association, Steel Treating Research Society; Standardization Committee of A.G.M.A.; Member of Canadian Engineering Standards Association.

machine. The gear and the tools are compelled to roll in mesh without slipping, by a master segment, selected to suit the pitch angle of the job, and held in mesh with the crown gear segment which controls the shaper mechanism. The action is exactly similar to the two steel tapes in the Fellows cutter generating grinder.

In the case of the Gleason "spiral" bevel generator the construction is more obscure, but the principle is similar. While the tooth is curved in profile, a line at any point along the tooth would show a true involute curve. The cutter section, taken perpendicular to the cone is a side mill, somewhat of rotary planer style, with inserted teeth ground to the required gear tooth pressure angle, and with tip flattened for the width of gear tooth space at the root of small end of teeth. This cutter being set with its face parallel the root angle of the gear to be cut, is fed axially into the blank to the required depth and then gears and cutter are rolled in mesh, the action being that of a gear rolling in mesh with a flat crown gear which occupies the same plane as the cutter, which is generating the teeth.

The literal use of the rack itself as a cutting tool is seen in the Sunderland gear planer used in England for spur and helical gears. On account of the special construction of some of these machines which allow the shaper guides to be swiveled about at any angle it is possible to cut helicals of high tooth angle and therefore of any shaft angle. The Fellows is limited to angles not too far from parallel the shaft, and of course to the standard angles for which the machine is equipped. Both the Fellows and Sunderland will cut close up a shoulder, which is impossible with a rotary cutter or hob, but they also require a chip space turned in the metal between the gear and the shoulder, down to root diameter. There are other machines in use on the continent of Europe based on the same principle, and Bilgram has made a spur generator using a tool to correspond with a rack tooth. None of these are in general use in North America, nor can they compare with the Fellows or the hobbing process for general and practical efficiency.

Hobbing Process

The hobbing generating process is adapted to the spur, helical and worm gears, and in special machines to worms. The hob is of the general form of a worm, made of tool steel, gashed to provide cutting edges, relieved back of the cutting edge, hardened, and ground on the face of the tooth. By reason of the relief, or reduction in diameter back of the cutting edge, which is made by a formed tool controlled by a cam in finish turning the hob, the form of cutting edge is unchanged by repeated grinding on the radial face. Also by reason of this same reduction of diameter, the helix angle of an old hob is materially different from a new one, and a correction must be made by setting the hob axis in the machine at a different angle to the tooth to be cut.

A hob cuts gears by two methods. First, it may cut a worm gear by impression, that is, by sinking the hob the required depth into the rim of the gear blank, using only the one feeding motion in addition to revolution. Here the hob simulates the worm which is to operate with the gear when finished, and must closely resemble it in external dimensions. The direction of feed may be either radial or tangential to the gear blank. The former is the common way, but the latter is the more accurate and rapid, but requires special machines.

Tangential Feed of Hob

The tangential feeding of the hob is not a simple traversing, but is accomplished by a special train of gears connected through a set of differential gears with a train that revolves the work table, so as to impress upon the revolving work an increment of rotary motion equivalent to the tangential feeding motion of the hob, said equivalency being reckoned at the pitch line. If this were not so, the feeding of the hob tangentially to the work would merely mill out a concave groove. In other words, the hob is not fed in a simple lateral movement, but is screwed along its own helix. Hobs for this work are usually made tapered at one end as to outside diameter so as to start cutting gradually on a number of teeth, resembling somewhat a taper tap. The taper is not applied to the pitch and root circles. These special machines, equipped with differential gears for tangential feeding of hobs will also generate perfect worm wheels without any hob at all, by the use of a fly cutter, shaped to the thread cross section and radius of the worm. As the cutting proceeds the tool is fed tangentially to the work with a motion of being screwed along the helix of the imaginary worm. If the worm is of multiple thread there are two alternatives: either the cutter arbor may carry two or more tool points, suitably spaced, or after one series of tooth spaces have been generated, either the work or the cutter may be rotated by hand one tooth space and the next series generated. Like all fly tool work, this is a slow method and only used in the absence of a suitable hob.

Another Hobbing Method

The second method by which a hob may generate teeth is by simulating a rack, with its cutting edges, and being fed to the work in a direction parallel the work axis. The rack which it simulates is not perfectly straight but really an arc of very long radius, but the generating action is the same. This is because the hob must have its thread parallel the teeth being cut in the work and obviously the plane of generation is perpendicular to both. This plane then cuts the pitch cylinder of the hob in a long ellipse, whose minor axis is the pitch diameter of the hob, and whose major axis is a function of the diameter and the helix angle of hob thread.

In cutting a gear the hob is placed with its axis at such an angle that its thread is parallel the teeth to be cut. The radial depth to be cut is a matter of preliminary adjustment, there being no feeding in this direction. The feeding is all parallel the work axis, not directly along the tooth being cut except in the case of spur gears, thus preserving the cylindrical form of the gear. Straight line feeding along an angling tooth would produce an hyperboloid of revolution, which is referred to elsewhere under "Skew Bevels." In the case of helical gears it is, however, necessary that there should be a virtual feed along the helix of the gear tooth. This is accomplished by modifying the gear ratio of the machine. In cutting spur gears the gearing is simple and direct. The work is revolved in direct ratio to the hob, based on the number of teeth in the gear and number of threads in the hob. In the case of helical gears the advance of the work will be greater or less than 360 degrees of arc at the end of each complete cycle of tooth cutting, by an amount dependent on the tangent of the helix angle of the gear tooth, and the distance the hob has been fed parallel the work axis. This advance increment is provided for in one of two ways. The feed that is to be used on the job may be assumed and the increment calculated and the gearing in the train that drives the work modified from the simple ratio to the ratio which will give the new advance. This is difficult, and it is not always exactly possible within the mechanical limitations of the machine and the change gears available,—and in any case a change of feed means a complete recalculation of the set-up of change gears.

Differential Gear Method

The other way is to use the differential gear method, somewhat in the same way as mentioned above for tangential feeding of worm hobs. In this case, for helical gears the hob feed, which is parallel the work axis, is connected through a differential to the gears that rotate the work. Thus the work, in addition to being given a rotation by a train from the shaft that drives the hob, is also given a small increment of rotation from the feed mechanism. The differential method is much the better, as the feed can be changed at any time, and both the calculation and the setting up are easier. Unfortunately, it has been controlled in the United States by Schuchardt and Schutte patents, which, due to peculiarities of United State's patent law, they have not been compelled to work. The result is that American hobbing machines use the awkward and roundabout method.

The hobbing process is a rapid one, and good hobbing machines are fast

Machining Engine Parts for R-S. Motorcycles

Jigs and Fixtures Used in Various Operations—Method of Resisting Strains—Locating Work by Sliding Wedges—Machining the Gear Box—Jigs of Compact Construction

By ROBERT MAWSON

THE Reading-Standard motorcycle is manufactured in Reading, Penn., and in this article will be shown the special tools and their use described when machining the cylinders, 3-speed gear box, connecting rods and cams used in the making of this motorcycle. The R-S motor is of the high speed, long stroke, four cycle type, having a 4 inch stroke, cylinder bore of 3⅜ inches, with a piston displacement of 71.57 cu. inches developing 16 actual horsepower. The cylinders are made of high-grade gray iron of the sloping head type with the spark plug placed in the side of the valve chamber, one of the finish machined elements being illustrated in Fig. 1, this being the front cylinder for a machine.

The first machining operation on the cylinder is performed with the set up as shown in Fig. 2. The casting is located and held in the special fixture A, being located by means of vee-blocks which come against the round section of the piece with the swinging cover B fastened down to the stationary or fixed portion with the bolt as shown. Four set screws C, 90 deg. apart are then tightened against the cylinder to hold it firmly in the fixture, the casting having been pushed back against a stop at the rear of the fixture which assists in resisting the strains during the machining operation and also enables the man to machine all the pieces to the same length over all. With the cylinder as shown it is bored and reamed to 3⅜ ins. leaving 12 thousandths of an inch for a later grinding operation; both sides of the flange are faced and the register projecting from the flange turned to 3⅝ inches. The tool for boring may be seen at D, the reamer E, and the combination tool F which faces the two sides of flange and turns the register. This last tool is made so that the operator feeds in from the outer edge and a cutter faces one side and another cutter the other side of the flange to the desired thickness and as the cutter head is fed in further the register is turned to the proper diameter.

Machining Valve, Plug and Flange Holes

The half tone shows the jig for the next operation. In this tool the cylinder is located by the turned register on its flange which fits into a machined recess in the base of the jig, and also by sliding wedges which are tapped in lightly against the sides of the flange to bring it into the desired and proper position, the wedges also tending to hold the part securely in the jig. The following holes are then machined, two 1¾ inch bored and reamed in the position as shown for the valve seats, one to suit a ⅝ inch S. A. E. thread for the spark plug through the bushing B, one for ¾ inch S.A.E. thread for the cylinder plug through the bushing C, and two 9/16 inch and four ⅜ inch in the flange, the jig of course being moved to the different positions on the table to suit the machining of these various holes.

Machining the 3-Speed Gear Box

A view of a finish machined 3-speed gear box is shown in Fig. 4. This unit is of the sliding gear type, the main shaft is mounted on over-size ball bearings and carries the high, sliding and low speed gears. The secondary gears are made of one-piece drop forgings, the three speeds being integral. The gear ratio in the transmission are for high, 3.91 to 1; intermediate, 6 to 1; low, 9.20 to 1 and in the case oil leakage is eliminated by the use of heavy felt washers. Figs. 5 and 6 show the jig for drilling the 3-speed gear box, the casting is located by a large pin that fits into one of the large cored holes and the piece is then swung around against a stop.

The following holes are then machined, all four sides of the jig having bushings to guide the various tools—drills and reamers. Six No. 11 for the high speed ball bearing housing, four holes to suit ⅜ inch studs, one ¼ inch drain plug hole, one 9/16 inch, two 1 inch drill and ream, one 1-1/16 drill and ream, one ½ inch ream, and two 13/64 inch drill. It will be noticed that the jig is quite compact, the piece being held in from the ends, two of which are open so that the chips can fall away from the casting so that they will not interfere with the accurate setting of the part in the tool.

The illustration Fig. 7 shows a fixture used to hold the gear box when performing certain spot facing operations. The piece is located by two plugs A. and B. which fit into a one inch and a half inch reamed holes machined in the previous operation. The following work is then performed: spot facing for the lock shaft, spot facing the counter shaft flange, and also spot facing for the kick

Jigs and Fixtures Used in Machining Motorcycle Parts

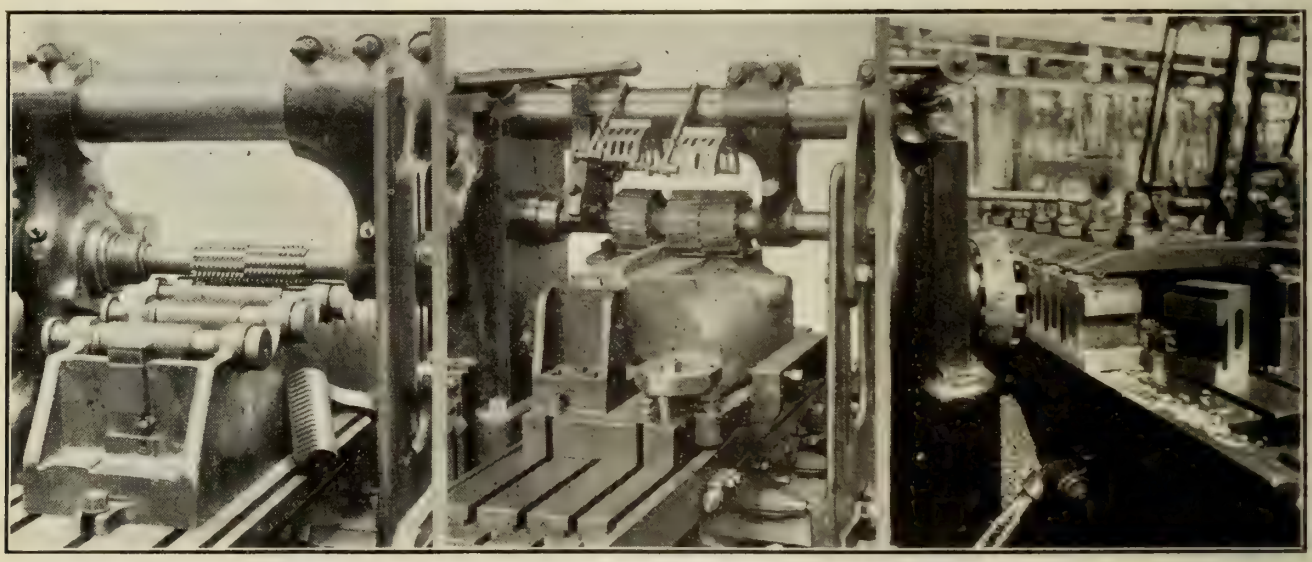
Milling Machines Show Production Results

The milling machine is making rapid progress as a production factor in the machining of large surfaces at speeds surpassing those previously recorded on other tools. Three interesting operations are shown here, the work being performed on Herbert Machines.

The view on the left shows the milling of rack teeth on phosphor bronze gluts for draw-in chucks used on capstan lathes. A special fixture is used for holding the pieces, with sufficient depth of box to take the extending arms of the glut, the cylindrical portion of which is supported on an arbor passing through the central hole. A gang of two annular hobs is used, the diameter of the hobs being 3 in. and the total length of rack 6 in., 8 diametrical pitch. The cutter spindle operates at a speed of 97 r.p.m., with a feed of 13/16 in. per min. Work is finished at one cut.

The centre view shows a milling operation on the base of the headstock for a capstan lathe. The surfaces are machined at two separate chuckings—roughing and finishing. The cutters are 6 in. diameter with inserted blades; the roughing cutters operating at a spindle speed of 20 r.p.m., and a speed of 39 r.p.m. for finishing. This gives a surface speed for cutters of approximately 31 and 61 ft. per min. respectively for roughing and finishing. The rate of feed for roughing is 2¾ in. per min., while a feed of 3 7/16 in. per min. is used on the finishing cut. On this class of work it is best to use a comparatively slow spindle speed, so that a batch of castings can be completely machined without having to break down for grinding. When being milled these bases are supported in a special fixture that minimizes the time required for setting up. It will be noted also that the table is prevented from working sidewise under the action of the cut or accidental movement of the cross feed handle, by the use of small adjustable jacks placed between the table and the supporting member of the overhanging arm. Similar jacks are used on the inner side to maintain maximum rigidity. Cutter guards are for protection of operator.

The operation shown at the right is the face milling of tool boxes for roller steady turners for hexagon turret lathes. One of these steady heads is shown to the left of the cutters in the center view assisting to support the arbor against the thrust of the cut. These tool boxes are first made in long pieces and afterwards cut into short sections which require to be milled on the ends as here shown. At this operation no special fixtures are employed, the work being clamped down to the table with ordinary shop tackle and set up against a strip in one of the tee slots. The face cutter is 9 in. diameter, operating at a spindle speed of 25 r.p.m. under a feed of 2 3/16 in. per min.



MACHINING ENGINE PARTS

(Continued from previous page.)

starter shaft bushing, all three surfaces being on the upper side of the casting as it is shown in the illustration.

Machining the Connecting Rods

The connecting rods are made of drop forged steel and as is the common practice in motorcycle construction have the center one fitting inside a forked type of rod, which enables the building of the machine more compact. The half tone Fig. 8 shows the jig used when boring the connecting rods, both the solid and forked pieces being machined in similar types of tools. The forging is located by means of a fixed vee block at the large end and a sliding block at the wrist pin or small end. On the center rod a 1-13/16 inch hole is bored and reamed at the large end and a ⅞ inch hole drilled and reamed at the small end. On the forked rod the hole at the large end is 1-9/16 inch and a similar size of hole drilled and reamed at the small end as that machined in the center rod. The reason for the difference in size between the center and forked rods is that the center rod is fitted with a bushing in a later operation, the hole of which is 1-9/16 inch, the bushing being cheaper to replace than an entire rod and as the bearing is shorter tends to wear more rapidly than the forked rod with its much longer bearing. One of the center rods is shown at A. and a forked rod at B., both of them having been bored and reamed in the operation here described.

At this plant they have a rather interesting method of making the cams which operate the inlet and exhaust valves on the motor. These are made of solid forgings, and are first accurately machined as shown in Fig. 9 at A. This is then placed in the chuck B. which centers it by its outside diameter and the cam profile machined as may be seen better by referring to Fig. 10. At A. is placed a form plate with a similar contour to that desired to be reproduced on the cam only of larger size to reduce any chance of variation. A weight is suspended from the lever B. to hold the milling cutter and cam in contact so that as the worm wheel C. is rotated and also the cam which is attached to the worm wheel member, by the action of the worm D. which is revolved by the belt shown on the right, a similar shape is machined on the forging as the former possesses.

After both cams have been machined, one on each side, one for the intake, the other for the exhaust, the teeth are machined on the blank, thus making this important part of the motor integral, and preventing accidents which might happen by cams slipping if fastened on the gear with keys or other mediums.

Benefit Society Develops Plant Fellowship

Has Been Functioning for Thirty-Nine Years in Connection With Goldie & McCulloch Co.—Surplus Funds Distributed—Some Employees of Long Standing—Industry Has Had Steady Growth

ALTHOUGH not altogether as hoary with age as one might expect by reason of its association with the parent firm, the Goldie & McCulloch Benefit Society can at least boast its 39th birthday, and that is quite an age, as benefit societies go. It was organized in Galt in 1883 as the Dumfries Foundry Benefit Society, and this name, indicative of the original title of the industry with which it is associated, was retained until one year ago when it was changed as above. The number of employees at that time was about 250, whereas to-day the staff has more than doubled. There were then a dozen men employed in the foundry, where now there are fifty, and the plant is easily four times its size at the time the Society was organized. The product of the Company consisted of engines, boilers, flour, woollen and sawmill machinery, besides elevating equipment, a line that was quite as representative of industry as it flourished throughout the province some forty odd years ago, as the lines to-day are an index to the great strides that have been made in engineering since that time.

The Benefit Society had its birth in the idea that, whereas subscriptions were from time to time taken among the employees to assist any of their number known to be down in his fortunes, it finally seemed advisable to conduct this work in an organized way. It was evident, occasionally, that the spasmodic subscription idea did not always include men who were quite as worthy, but whose misfortunes were not always as widely known as others. Hence it seemed well that in the movement there was embodied the plan that would make relief available to all alike.

Of the original members of the Society, three are still in the employ of the Goldie & McCulloch Company, H. H. Biggs, the present secretary, employed as shipper; Robert Baird, clerk of bill of materials, and Robert Hunter, foreman moulder. These three men have each been in the employ of the Company for more than forty years.

The membership of the Society has always averaged fully seventy-five per cent. of the staff. By way of benefit, a member receives 66 2-3 cents per working day for the first thirteen weeks. He is not entitled to such, however, until he is six working days from work. If four weeks sick, he receives pay from the first day's sickness and 33 cents per week for the second thirteen weeks and day for the second thirteen weeks and 25 cents per working day for the next 26 weeks, after which membership ceases. By paying dues, however, the member is entitled to free doctor and a funeral benefit of $50. In the event of death this latter amount is paid to nearest relatives, and if there are none such, this amount goes to those taking charge of the funeral.

On their admission, members pay 25 cents entrance fee. Regular dues are 25 cents twice a month, payable at noon the day succeeding pay day, but if necessary an extra levy may be made. To be entitled to benefits, every member must be one month in the Society. Among other duties, the treasurer is required to post in the shops the Monday following each pay day the names of those reported ill, number of days and amounts paid each, together with total receipts and expenditures for the previous two weeks, and balance on hand. The executive committee of the Society exercises a general supervision of the Society's affairs, collects the fortnightly dues from the respective shops, visits the sick on order of the president, invites new workmen to join and to have full power to admit or reject applicants. The treasurer receives at the rate of four per cent. and the executive two per cent. for all monies paid in, except on entrance fees.

Every employee of the Company is eligible for membership, provided he is in good health and of strict moral character. The Society doctor receives $1.30 per member per annum. He attends sick or injured members and provides them with proper attention. If able to walk, the sick member is expected to attend the surgeon and not require him to call. In surgical cases requiring a specialist the member, of course, pays for the specialist. If the surgeon neglects the patient, whatever sum is due him from the Society will go to pay the expense the member has been put to for another surgeon.

Apart from the membership fees, the Company makes a yearly contribution of $200.00, one-half of which goes into the general fund and one-half toward the annual picnic. Balances on the last item are returned to the funds. Apart from a reserve fund of $100 retained in the treasury at the end of the year, the amount remaining is divided proportionately, according to the period of membership.

The society has no relation, whatever, to the workmen's compensation law and finds as one of its chief benefits the feeling of fellowship which it has developed among the members of the staff and their families. The annual picnic is therefore, a pleasurable event. The present officers are: Hon.-pres., R. O. McCulloch; hon.-vice-pres., A. R. Goldie; president, J. Stewart; secretary, H. H. Biggs; treasurer, W. C. Sass; managing committee, one from each department of the works: carpenter shop, R. Keller; machine shop, W. J. Wilson; engine shop, F. Rayfield; moulding shop, J. Seville; boiler shop, C. Hirst; blacksmith shop, W. Dickson; safe shop, G. Bates; office, J. H. Unwin; box shop, D. McDonald. Auditors, W. Herriott and E. R. Scott.

CANADA'S TRADE MIDDLE EAST MARKET

DISCUSSING Canadian trade opportunities in the market of the Middle East, Trade Commissioner P. W. Ward, writing from Singapore, Straits Settlements, states:

Certain export houses in the Dominion have been very satisfactorily linked up with this market for a number of years, and substantial business has accrued. If manufacturers of articles, which will be definitely indicated in a later report, will apply the same concentrated effort and carefully follow the lines on which business can be obtained—and will be fully described by the writer—Canada's trade with the Middle East can be rapidly extended and the annual figures many times increased.

A fault in evidence with many exporters, however, is that they appear to be unwilling to use the present moment to plan for the future and go to the trouble, at this time, of carefully studying normal market prospects and negotiating relationships with buyers and importers against the day of returning trade. So many seem to be unattracted to anything which does not mean immediate results. The market of the Middle East is one which cannot be cultivated overnight, and a real study of conditions, with patience and carefully supervised methods, is necessary if success is to be obtained.

During the next few months the basis of trade in this territory will be laid for some considerable time to come, and only those who grasp the present opportunity are likely to share in the splendid returns which returning trade will bring.

The territory under consideration has a population of 76,200,000, a purchasing power, Canadian currency, of more than one billion dollars and total annual imports on which Canada can compete, of $173,800,000. The countries comprised in the review of trade conditions are: Straits Settlements, federated and unfederated Malay States, Siam, Netherlands, East Indies. Br. North Borneo, Sarawak and French Indo-China.

Efficient Handling of Work Facilitates Output

Local Needs a Guide to Equipment Used—Conserving Man-Power An Item of Economy—Trucking Aisles Should Be Kept Clear—Proper Storage Racks a Great Advantage

FEW factors in the problem of quantity production are more difficult to reckon with than the handling of material during the process of manufacture. The question of which is the best method is one that must be decided by the nature of the product, the volume produced, the layout of the plant, and the efficiency of the equipment available for the purpose. The individual operations of each machine and the skill of the workmen may be all that is desired, but unless the efforts of each man and machine are co-ordinated with one another, and each department working in harmony with all others, the aggregate efficiency may fall considerably below that of the average workman or machine.

Movement of Material

A very important item in the scheme of management is the system of moving the raw and semi-finished material from one location to another. It matters not whether this be the handling of work to and from a certain machine, from one machine to another, or from one department to another, the question is one that must be given careful consideration to assure the highest possible results from an economic standpoint. Where large quantities of material are constantly moving about in an extensive plant, undergoing a diversified number of detail machining and assembling operations, the labor involved is frequently an item of no little magnitude. The secret of profitable manufacture is largely a matter of keeping this handling cost down to the lowest possible minimum.

Illustrations through courtesy of Lakewood Engineering Co., Cleveland, Ohio.

The most essential and likewise the most obvious detail in regard to effective planning for quantity manufacture, is the layout of the plant and equipment so that the progress of the work will be continuous in one direction with little or no overlapping or backing up. When such a plan is adopted the cost of handling is greatly reduced.

When a certain machine is engaged in doing a detail operation—one of many on a certain piece of work—and large numbers are passing through, it is necessary to place them to one side while awaiting removal to the next machine. The old method of piling the pieces on the floor is gradually being superseded by other methods which eliminate the double handling that formerly added to the cost of manufacture. How easily many of us can look back and see the workman taking the piece from the machine, place it carefully—or otherwise—on the floor, and after doing the same with many pieces, watch another workman come along with a barrow or a truck, lift each piece separately onto the platform until it is fully loaded, wheel it away to another part of the shop and deposit the pieces, one by one, on the floor adjoining the machine that is to do the next operation. Few modern shops would tolerate such practice to-day.

During the past few years the question of factory transportation has received considerably more attention than that accorded it prior to the age of shells. During the period of excessive activity industry was forced to work under the handicap of a shortage of labor. This together with the necessity of efficient and rapid transfer of material about a factory, gave tremendous impetus to the better trucking methods that are now recognized as an imperative need in even the smallest of manufacturing plants.

Movement of Product

Second only to the systematic layout of equipment are the facilities provided for the movement of the goods through the various departments. Machines should not be crowded together. Ample space is required for the placing of work as it is brought to and taken from the machine, and this must not interfere with the space reserved for general truck movement in the shop. Interference is the one outstanding feature that must be avoided in shop conditions. If a truck load of parts is moving through a shop and is required to stop in its passage while the workman removes some obstruction, this interference momentarily disturbs other workmen in the vicinity; perhaps one or more is required to assist the truckman in clearing the passage—while others look on. Wherever trucks are employed it should be an understood rule that the passage reserved for such trucking must be kept clear at all times. If necessary provision should be made to prevent the truckman from trespassing on the territory of the other workmen, and vice versa.

Conserving Man-Power

In large plants where the handling of heavy sheet metal stamping and forming dies are used considerable time is required in taking the dies and bolsters to and from the storage rooms and presses. Unless adequate trucking facilities are provided for this purpose the labor cost runs into large figures owing to the number of men required to

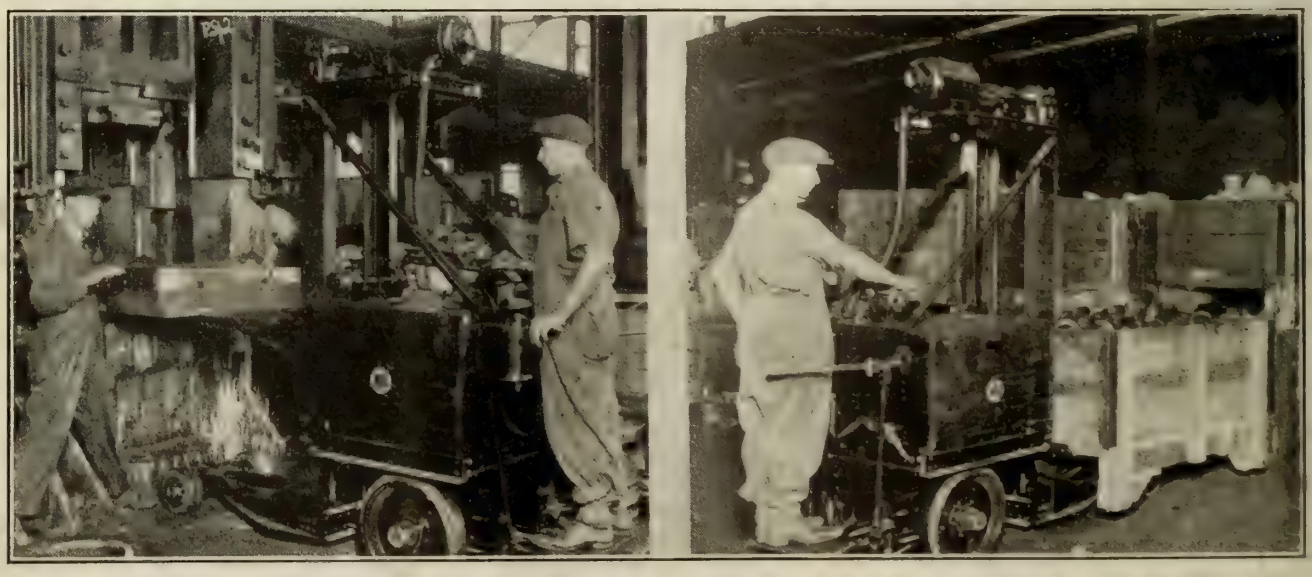


Fig. 1—Left: Tier-lift press removing large die from press. Fig. 2—Right: Handling large loaded crates of sheet metal stampings.

handle the heavy masses of iron and steel. By the use of tier-lift appliance the labor effort is reduced to a minimum, and the time consumed in placing and replacing dies permits of greater efficiency in the output of men and machines. Not only is it a great saving in time, but tools are subjected to less rough usage through the convenience of operation. Fig. 1 shows a tier-lift truck with the platform raised to the level of the press bed so that the die or bolster is easily pushed into place beneath the ram or removed from the press to the truck platform. This type of truck permits of storage racks being arranged so that the minimum amount of space is required for keeping the dies and at the same time provides adequate protection to all cutting edges and delicate mechanisms.

Saving Effected

Results of studies made by engineers in die handling metal stamping plants have shown that large savings can be effected by the adoption of equipment that will conserve the time of the workman in the handling of tools and product during the non-productive period. It is stated that from two to five hours is the usual time required for changing dies in the drop forge room, several men being used for the purpose. Under the old method of man power doing all the work the annual aggregate cost of changing dies in a certain plant amounted to over $33,000. In the installation of tier-lift trucks and proper die storage racks, the cost of the work indicated above was reduced to less than $2,000 per year. Fig. 2 shows a tier-lift truck handling large crates of metal stampings. These crates can be piled three deep if necessary.

The same reasoning applies to many classes of industrial plants where the labor cost for handling is a big item. Fig. 3 illustrates the use of lift trucks in a heat-treating plant, where the platform can be run right into the furnace to lift the rack that carries the work. Fig. 4 shows the application of the electric truck in a large foundry. These trucks and trailers are easily negotiated in narrow aisles on the moulding floor.

VARIED PRACTICE IN GEAR PRODUCTION

(Continued from Page 37)

producers, but the process labors under two difficulties. In the first case, as to accuracy of tools, it has the same status as the formed cutter process, in that its cutting tools are usually hardened after forming. All the distortion and shrinkage resultant from heating and quenching are reflected in the quality of the work. The nature of the hobbing process is such as to exaggerate these errors in the work, while the rotary cutter process minimizes them. Lately methods have been devised for grinding hobs all over after hardening. This is difficult and expensive on account of the form and relief, but if well done it eliminates a large part of the objection to hobbing. It does not, however, place it on a par with the Fellows process, no matter how perfect the hob, for the hobbing process has the inherent defect that it does not produce a smooth tooth curve, but really a series of flats. The sides of the hob teeth in the involute system are straight lines. The number of flutes in the ordinary hob is small, ten or twelve. The number of teeth of the gear actually being cut at any instant is the same as the number that would mesh with a rack, from one to three or four in ordinary gears according to size. It is plain that each hob tooth makes a flat cut and by the time the next hob tooth makes its cut the gear has advanced a definite angle.

The whole working surface of the tooth then is made up of from ten to forty, or so, flats. This is bad enough with a gear, but is evidently at its worst with a pinion. Now suppose the hob is warped, and all hobs warp more or less in hardening. It is quite possible for a pinion tooth to be so badly affected by the flats that result from the high teeth of a hob with a few flutes, as to be quite misshapen, as well as presenting a very bad surface. Good hobs with numerous flutes will produce good gears and fair pinions. The Fellows or Gleason systems on the other hand, since they cut the full face of the gear at each stroke, have a very slow rate of rotation, and what correspond to the flats of the hobbed pinion are only a series of fine scratches. Further, the condition is not markedly worse with a pinion of few teeth than with a gear. It should be mentioned here that the disadvantages due to flats disappear in the case of the worm wheel hobbed by the tangential feed method, for while this hob would generate flats in any one position, as soon as it is moved along the tangent to the work it wipes out all flats and leaves a perfect job. Defects due to hob warpage are also minimized in this particular case.

(To Be Continued)

EFFICIENT ENGINE INDICATOR

Engineers have the greatest possible regard for the simple indicator which has been used for so many years to reveal what is happening inside the cylinder of a steam engine. The indicator diagram of an engine is the recognised certificate of character. This standard instrument, however, is not exempt from the law of progress, and at a recent meeting of the Royal Society of Great Britain an instrument was shown which quite puts the old-fashioned indicator in the shade. This instrument will, within half a minute and almost automatically, produce ten successive permanent records of the performance of a high speed engine. It traces these records on a card which is ready either for immediate inspection and measurement in a very simple microscope, or for photographic enlargement. The value of such records taken at such rapid intervals is that they draw the attention of the designer or manufacturer to unsuspected or obscure defects which would not be revealed by the ordinary indicator. The new indicator can be used on motor cars and on flying machines when track tests or trial flights are being conducted, and where there is neither space or time for elaborate instruments or methods of testing. The records are mechanical, not optical or photographic, and the operator need not leave his seat in order to take them.

News From the Welding Field

Oxy-acetylene Welding and Cutting Blow Pipes

Tests of Different Apparatus—Weighing Quantity of Gas Consumed—Accurate and Fair Records Should Be Kept—Better Understanding of Blowpipe Flame Necessary to Economy

By ROBERT S. JOHNSTON

AT THE request of the Standardization Section, Purchase Branch, Purchase, Storage, and Traffic Division of the War Department in the States, the Bureau conducted an investigation of the operation, efficiency, and safety of oxyacetylene welding and cutting blowpipes. Apparatus from fourteen different manufacturers were submitted to test. The tests were decided upon after a careful survey had been made of the technical literature on the subject and a thorough study made of the various operations in which these blowpipes are used. Suggestions for methods of tests were also secured from the manufacturers.

All blowpipes were submitted to a standard series of tests, which were developed with the idea of minimising the personal equation of the operator and securing data that were representative only of the blowpipe itself. In order to accomplish this result a rather elaborate testing equipment, consisting of a weighing system, a gauge-board equipment, welding table, cutting table, and safety and flashback testing apparatus, was designed and used throughout the investigation.

Gas Consumed

The weighing system was used to determine the amount of gas consumed in any blowpipe operation, the process consisting in determining the loss of weight of banked tanks of oxygen and acetylene. In order to transfer the loss of weight into cubic feet of oxygen and acetylene consumed, special studies of the density of oxygen and acetylene were made. The gauge-board system comprised a flow meter designed and calibrated for this investigation, which was used to furnish a check upon the quantity of gas consumed in the welding and cutting operations, and also to secure data that would show the fluctuation of gas volumes used at different periods of time during a test.

Special care was taken to furnish the gas delivered to the blowpipes at the pressure specified by the manufacturers. To accomplish this, special compound manometers were designed and used throughout the investigation, Bourdon tube gauges being used only as a check apparatus. Besides observational data of the gas volume being consumed as indicated by the flowmeter differential manometers and the pressures delivered to the blowpipes, autographic recording gauges were also installed to secure graphical representation of the pressure fluctuations.

Welding Tests

All welding blowpipes were submitted to welding tests on ½in. and ¾in. metal. The operation of the blowpipe, however, was necessarily performed by experienced operators. For the cutting tests the blowpipes were mechanically guided and controlled, so that practically all personal equation of the operator was eliminated. During the cutting tests the blowpipes were operated at the maximum speed at which they would cut metal of specified thickness. ½in., 2in., 6in., and 10in. metal were used in the cutting tests.

A further series of tests was made to determine the freedom from flashback and safety of operation of the various welding blowpipes.

The results of the initial series of tests carried out on the welding blowpipes indicated that there were some phenomena in connection with the operation of a welding blowpipe that were not understood. A very thorough study of the design of the various welding blowpipes was therefore made, and certain conclusions relative to the cause of inconsistencies in action noticed were arrived at. A supplementary series of tests was then carried on to prove the correctness of these conclusions. From this secondary investigation it is shown that the proper principles upon which the design of oxyacetylene-welding blowpipes should be based were probably not fully realized. The results of this entire investigation may be summarized as follows:

Cutting Blowpipes

1. There is to-day no generally accepted theory for proportioning, for the cutting of metal of various thicknesses, the volume and velocity of the issuing cutting jet, with the result that none of the apparatus submitted to test proved economical for all thicknesses.

2. There is for any thickness of metal cut a limiting velocity of exit of the cutting jet at which complete utilization of the oxygen takes place, and there is a limiting value for the amount of oxygen required to produce a cut.

3. An increase in acetylene consumption, in oxygen consumption, or in the velocity of exit of the cutting jet beyond the limiting value, does not produce increased efficiency in commensurate ratio.

4. A large majority of the blowpipes tested were equipped with excessive preheating flames for the thickness of metal the tip is specified for, and such excessive-sized flames are disadvantageous both from the standpoint of economy of operation and quality of work performed.

5. Considerable improvement in economy of operation seems possible in cutting material of 2in. thickness; possibly this condition may be found to exist for metal of other thicknesses than those used in the tests.

6. The maximum thickness of metal that may be economically cut with an oxyacetylene blowpipe of standard design, when neither the material nor the oxygen is pre-heated and the cutting is done from one direction, is about 12in.

7. Cutting blowpipes, due to their incorrect design, are subject to the same flashback troubles found in the welding blowpipes.

Welding Blowpipes

1. The blowpipes most subject to the so-called phenomena of "flashback" are those in which the oxygen is delivered at a pressure in excess of that at which the acetylene is delivered.

2. All blowpipes tested, including those in which the acetylene is delivered at an excess pressure, as well as the so-called equal or balanced pressure blowpipes, are subject to flashback phenomena on account of inherent defects in their design.

3. The cause of the development of the conditions producing flashback is the setting up, within the blowpipe tip and head, of a back pressure which retards or chokes off the flow of one of the gases.

4. This back pressure is the result of confining or restricting the volume flow of the issuing gases at the tip end.

5. Any cause tending to restrict the flow of the gases sets up a back pres-

Who Will Supply World's Steel Requirements?

Productive Capacities of Britain and America Considered—Will Immense Home Demand in U.S. Absorb Production—Heavy Transport Costs on One Side and Low Production Costs on Other —British Export Distinctly Upward

AS THE possibilities of American competition in the steel group of trades are provoking considerable speculation, attention may be called to some of the governing factors in competition between Britain and the United States in the heavy iron, steel, and engineering trades, writes a correspondent in the Manchester Guardian Commercial. From time to time America has been pictured as a country with the greatest natural resources, the most up-to-date manufacturing plants, the most efficient workmen, the cheapest transport, and the most pushful business men. Periodically we have been told that she was just about to undertake such an export campaign as would sweep our goods out of the markets.

The Americans, with their vast resources in coal and iron ore, built an enormous number of new plants. They put themselves in a mechanical position to produce more iron and steel than Britain and Germany put together. But they failed completely to capture the world's export trade. They manufactured in great volume for their own protected home market, but they could not touch either ourselves or the Germans in export trade. In the last fifteen years before the war Great Britain, with its relatively small productive capacity, sent to overseas markets nearly a sovereign's worth of iron and steel for every dollar's worth exported by the United States. We frequently saw mammoth steel plants in America, representing hundreds of millions of capital, standing idle while Britain and Germany between them divided nearly nine-tenths of the world's export business. Will history repeat itself?

Let us consider the productive capacities of Britain and America. In round figures these two countries could produce annually, with every furnace going, the following quantities:—

	Pig Iron tons.	Steel Ingots & Castings. tons.
United Kingdom	10,000,000	12,000,000
United States..	45,000,000	49,000,000

At the present moment they are producing at the following rates:—

	Pig Iron. tons.	Steel. tons.
United Kingdom	5,500,000	6,000,000
United States..	32,000,000	38,000,000

It is not, however, actual production so much as volume of exports that we are interested in from a competitive point of view. In round figures the current British and American iron and steel export rates per annum may be put as follows:—

Annual Rate of Iron and Steel Exports.

United Kingdom..... 3,500,000 tons.
United States..... 2,250,000 tons.

In 1917, under the munitions pressure and with no ordinary competition to meet, America produced 43,500,000 tons of steel, and her capacity has been increased since then. But last year she produced less than 20,000,000 tons. From the low level of July, 1921, the American steel output has increased as follows, notwithstanding a coal strike covering April and May:—

U. S. Steel Output.

	Tons.
July, 1921	954,000
August	1,351,000
October	1,920,000
December	1,694,000
January, 1922	1,892,000
February	2,072,000
March	2,815,000
April	2,897,000
May (est.)	3,200,000

U. S. Exports Falling Off

The latest advice from America puts the annual rate at something over 38,000,000 tons of steel, with production likely to go still higher when the coal strike is settled. The possible effects of this huge output on international trade are not easy to forecast. Month by month since the middle of last year steel orders have grown on United States home account. They grew on foreign account until the coal strike and increased prices were threatened. Since then there has been a falling off in shipments, but a much more marked decline in fresh orders. Actual export tonnages have been as follows since the depression in the middle of last year.—

U. S. Exports of Iron and Steel and Manufactures Thereof.

	Tons.
July, 1921	85,000
August	73,000
October	102,000
December	130,000
January, 1922	157,000
February	133,000
March	204,000
April	198,000
May (est.)	150,000

Against these figures Britain has so far this year exported at the rate of 260,000 tons per month, with the tendency distinctly upward.

Large American Demand

As soon as the American coal strike was threatened there was something like a rush of orders for steel, and the mills are pretty well booked up till August at the current high rate of output. Prices have been advanced, roughly, by £1 a ton since the end of March. But will this activity on domestic account continue? Will home demands be nearly sufficient to absorb the production after, say, August? Or will there be a huge surplus available for export in competition with our products? And if so, at what price will American steel be offered? Fuel prices are inflated, owing to the coal strike, and the consequent steel price advances have brought bars and shapes to about £8 a ton in English money at Pittsburg. With the settlement of the coal strike, with fuel prices down, and with the 10 per cent. reduction in railway rates, how far will steel prices recede in the United States? Will they go low enough, assuming a big surplus for export, to enable American steel to carry transport costs from the interior of the United States to far distant markets in which we are interested, and finally be sold in such markets at prices under those of our products?

The United States proved during the war that she could export more than 6,000,000 tons of iron and steel in a year, Probably the country's transport facilities are good enough now for 6,000,000 tons a year. But it is chiefly a matter of cost, and on this point British and American conditions are opposite. We have very short haulage distances. The Americans have tremendous distances separating their ore from their coal and their plants from ports of shipment. Again, the British steel output per unit of labour is small compared with the American output. American wages are higher than ours per man, but cost per ton is less. The Americans have much cheaper fuel than we have.

To sum up, it may be said that while we have our coal and ore supplies, steel works and shipping ports almost side by side, in the United States the ore is deposited 1,000 miles from the coalfields, and the steel works, on account of the coal, are between 400 and 500 miles from seaboard. America's transport costs for minerals and heavy metal products are tremendous relatively to the free on board prices of the goods. The railway rates carried by a ton of common steel by the time it gets to tidewater in the United States amount to $9. We have the advantage in low assemblage and shipping costs; they have the advantage in low production costs—or labour costs per unit of output. We also have some advantage in the reputation we have for the soundness of our steel products. If we keep our fuel and other costs at something like current levels we can successfully compete in the heavy lines of steel and engineering, though we may be beaten in some of the lighter lines in which transport costs do not form a big proportion of the final selling price.

Practical Ideas From Practical Men

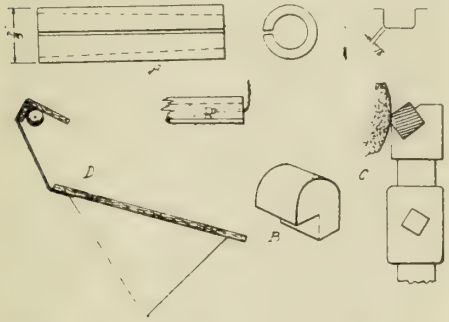
SOME SHOP KINKS

By D. A. H.

Job shops, more than others, suffer from the annoyance of drills being made both straight and taper shank. Each style of drill is all right of itself and fits into work schemes where the other will not, but when the shop has a typical stock consisting of one drill of each size from ⅜ in. up to 2 in. by sixteenths, there is sure to be a mixture of shanks. Job shops find the two-jaw chuck the best method of driving and changing drills—the chuck, of course, being designed for straight shanks.

Adapter For Taper Shank Drills

Collets with different combinations of sizes are on the market or may be shop-made (preferably the former) but there is one form of collet, or rather adapter, that is worth adding to the stock already on hand. It is shown at A. It is simply a sleeve with a taper



inside and straight outside, then split full length. This adapter may be made thinner than are stock collets and in that way will permit the use of the taper shank drills in smaller chucks. Another advantage is that it does not require the use of a drift. The sizes given are but one that may be made.

Bending in the Vise

There is quite a variety of bending and forming that may be done more conveniently at the bench vise in the machine shop than carrying to the blacksmith department. It is a frequent sight to see workmen hammering on the body of the vise in the rear or trying to bend round corners over the jaws—one is unexcusable abuse, the other is working without tools. Sketch B shows a simple little horn block that will save time and raise the standard of workmanship. Cast iron will do for ordinary purposes—once the pattern is made the pieces are so cheap that the shop can afford to discard when battered. The lower extension is gripped between the jaws; the horn part can be made to any curve desired or a variety of shapes gotten out that will answer every requirement as to height and radius.

Removing Corners of Key Stock

At one time we had a job that used a good many pieces of 7/16 in. square cold-drawn steel in lengths from 3 in. to 36 in. This is called "key stock" in many plants and we were using it as a removable key in keyways that were ordered cut with beveled corners. The bevel on the key had to be slightly greater than that in the keyway, for clearance. For a while we planed or milled off the two corners after the pieces were cut to length. This made a nice looking job but was expensive and to speed up the work we began to grind the corners freehand, grinding in the bar. This was quick but very uneven.

The work rest illustrated at C was made to overcome this weakness and it did enable us to do a nice job in quick time. Two pieces of steel were put together—one the shank of 1 in. c. d. s. and the other a square piece about 4 in. long forming the rest proper. In this latter, was milled a groove for the bar to lie in. The workman could not go wrong; there was space enough to manipulate easily but the angle was retained and too much could not be ground off unless the bar was deliberately lifted and held against the wheel.

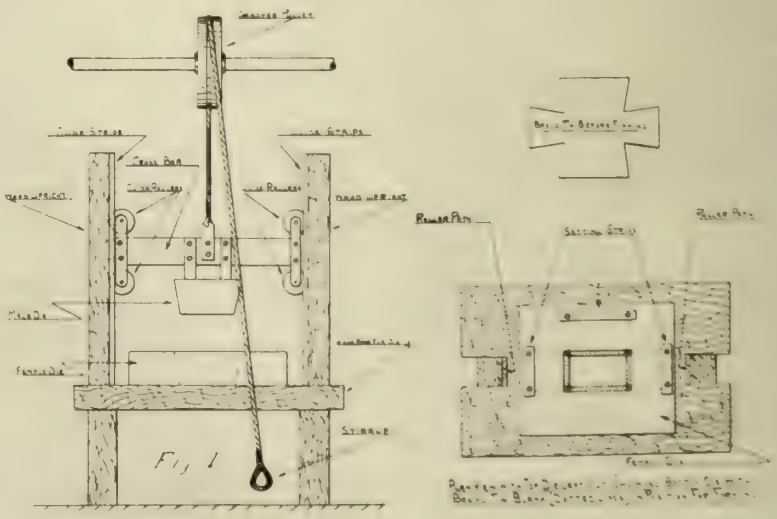
Shaded Light for Drawing Board

Drawing board light ideas have been about as numerous as ink bottle holders. As a good makeshift, if not for permanent use as well, the one shown at D is worth considering. Two pieces of board are joined in the form of an inverted trough. In the centre, at the highest part is fastened the lamp, which may be an extension or drop cord if not a line set in pipe. The interior is painted a flat white, the outside left unpainted or finished in dark color. A method of support adaptable to local conditions will suggest itself, the simplest being two upright boards at the ends which shut off light that way at the same time.

NOVEL FORMING DIE

By G. Blake

Although the making of bakers' bread tins is rather outside general engineering, yet on the other hand the devising of appliances and methods for economical production, provides scope for the tool maker. We recently had a contract to make a large quantity of bakers' bread tins; this type of tin is not folded at the ends, as is usual with these tins, but it is welded at the corners thus making an extremely sound tin. The first operation is to cut the corners of the flat sheets, which, by the way, were supplied the exact size so that they only required the corners to be cut out. The sketch in Fig. 2 shows the sheet after the corners have been cut out on the press; the next operation is the forming, or shaping, prior to the welding. A casting was made to the inside dimensions of the tin, this being the male die; see Fig. 1. Another casting was made to the outside dimensions of the tin, this being the female die block, see Fig. 1. At first it was intended to utilize an upright pillar drill, and to attach the male die to the drilling spindle and the female die to the circular work table, and to use the drilling spindle in the same manner as an arbor press and using the hand feed lever to press the tin to shape; this, however, did not work out successfully; and apart from its non-success, it was tying up a drilling machine which was often required for its ordinary work.



The writer got out a better method as shown in Fig. 1, the idea being taken from the well-known drop-stamping apparatus. A stout wood bench was made to support the female die block, it will be noted that there are two wood uprights on the ends of this bench, and, on these uprights, there were fixed by wood screws, mild steel guide bars two on each upright. These bars were set ½ in. apart; the cross bar, which is bolted to the studs on the male die, is a sliding fit between the guide bars. To facilitate and ensure easy movement, a couple of straps carrying four steel rollers (also running between the guide bars) were fixed to the cross piece; see Fig. 1. The studs referred to were screwed into the male die, a shackle provided the necessary link between the die and the rope for actuating the stroke. Fortunately, we had an idle length of line shafting fixed to the wall, this shafting was not used for transmitting power, so it was accordingly brought into use. The drop-stamping machine as described and shown in Fig. 1, was fixed to the floor under this line shaft, a special grooved pulley was attached to the shaft, the rope was passed over the pulley, and a stirrup was formed at the loose end; so that the boy, operating the machine could get his foot through it. By pressing his foot downwards he automatically raised the male die, and keeping his foot in the stirrup, inserted the plate as shown in Fig. 2; this plate was located by stops as shown, so that it was impossible to get it in the wrong way. To form the tin the boy simply raised his foot so that the weight of the male die being released it dropped down and formed the tin, he then pressed his foot down raising the die, took the formed tin and inserted another blank and proceeded as already described.

The feeding and delivery of the tins before and after forming is as follows: A small bench was placed at the right of the machine, upon which was placed (within arm's reach of the boy) blanks ready for forming and on his left hand was the work bench where the edges of the corners were hammered over prior to welding; the idea being that the boy operating the drop stamp would not have to move away from the work; he simply lifted a sheet with his right hand, placed it on the bottom die, formed it, and with both hands withdrew it from the die, and then with his left hand placed it on the bench for the hammering operator; meanwhile he would reach out with his right hand for another blank, it being understood that his foot would be continually in the stirrup, thus leaving his hands free as already described. The tins were thus formed cheaply and efficiently at a rate of 120 per hour at a cost of 8 cents.

MACHINING COILER WHEELS

By Geo. Barrett

The sketch, Fig. 1, shows a coiler wheel used to coil cotton into a round tin cylinder after going through the carding process. The first step in manufacturing these wheels is to face bottom side and cut groove; this groove acts as a bearing to hold the wheel in position on coiler stand and must be very accurate in dimensions.

Sketch, Fig. 2, shows the special chuck made for facing operation, and is a kind of a bell chuck having 3 steel lever jaws, A, 180 degrees apart as represented at front view, Fig. 3. In making this chuck, after fitting steel jaws, they are bored about 1/16 in. larger in diameter than the teeth on coiler wheel, giving the least possible movement when gripping work.

This chuck could be attached to any turret lathe or an ordinary engine lathe using air chuck or hand-wheel attached to draw rod, B. Fig. 2, for tightening purposes.

After facing and turning to diameter, the next step is to bore the hole which is on an angle of 45 degrees. This being done on an horizontal boring mill or engine lathe set for the purpose and using jig, Fig. 4, which is of the ordinary box type with the required angle. It is also bored out about ¼ in. deep at A, Fig. 4. To suit the diameter of work for truing purposes, the wheel is centered by scratching a line on outside diameter using an ordinary machinist's square for the purpose, and the mark being set to center line of jig. After clamping, the job is set ready for boring.

After boring, the next operation is to turn small diameter A, Fig. 1, also face same and put radius diameter inside of bored hole, the wheel being held similar to boring only using a lathe face-plate recessed out for the purpose. As the box must be of glass finish, the final operation consists of lead lapping inside of the hole to get the required smoothness.

OXY-ACETYLENE WELDING

(Continued from page 44)

sure which immediately causes a change in the amount of each gas delivered to the mixing chamber.

6. A fluctuating gas-volume ratio, due to restriction of volume flow from whatever cause, prevents a blowpipe from maintaining constantly and at all times during operation the desired "neutral flame."

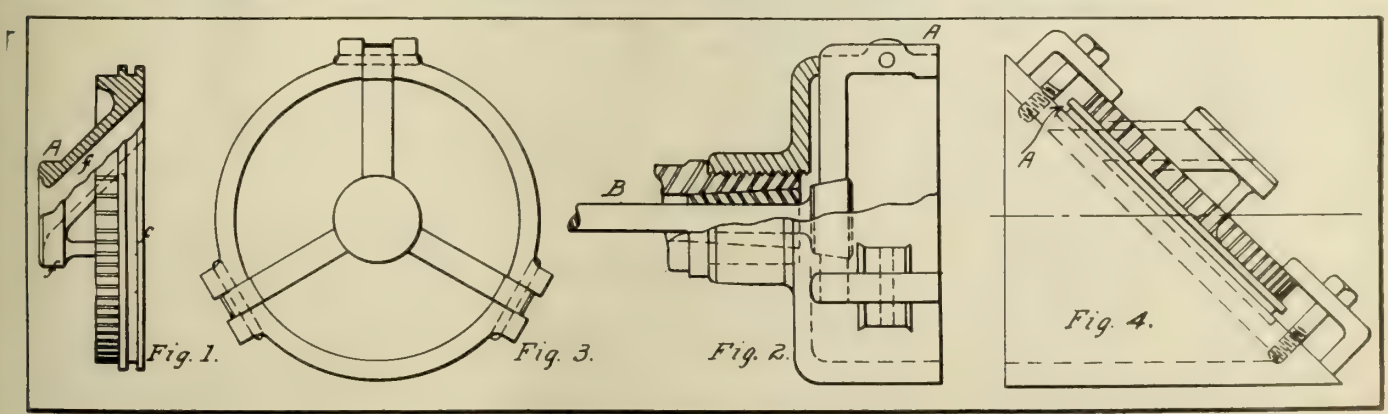
7. A blowpipe that cannot maintain under all operating conditions a neutral flame cannot logically be expected to produce sound welds.

8. All the blowpipes tested during this investigation either through improper gas pressure or improper interior design, or both, are incapable of maintaining a neutral flame (constant volume gas ratio) under all conditions of restricted gas flow, and are therefore incapable of producing sound welds where there is any liability of the gaseous products of combustion being momentarily confined, such as occurs in practically all welding operations.

9. The ability of a blowpipe to consume an equal ratio of gases when burning freely and undisturbed in air is no criterion that it is capable of producing sound welds—that is, that it is not subject to detrimental fluctuations in gas ratio during a welding operation, and therefore is capable of maintaining a neutral flame under all operating conditions.

10. Whether a blowpipe of present design will consume equal volume ratio of gases when burning freely and undisturbed in air depends on how nearly correct the operator sets the so-called neutral flame, and experience indicates that the average operator checks the acetylene-gas flow too much and actually develops an oxidising rather than a neutral flame.

Conservation of coal by the railways seems advisable and the Grand Trunk announces cancellation of a number of local trains. Main line services will not be affected.

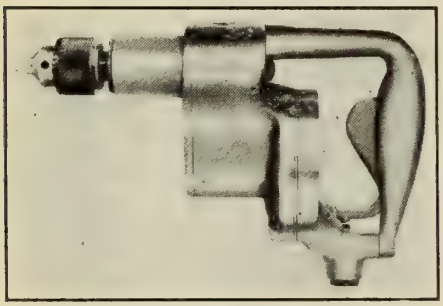


Method of machining coiler wheels.

New Things in Shop Equipment

TINY TURBINE DRILL

A specially designed light weight yet well-balanced and powerful air drill has just been placed on the market. The propelling portion of this tool is a turbine similar in character to some of the well-known turbines at present on the market, therefore, it is not an experiment. The turbine is made from an aluminum magnesium alloy having the strength of mild steel with about one-third of the weight. The speed of the



Lightweight Turbine Drill.

turbine being high, a gear reduction of considerable amount is necessary, likewise, the stresses on the gears are fairly high to meet these conditions, and insure long life. All gears and shafts are made from high carbon chrome nickel steel, oil treated, to insure the maximum physical ability. The tool is ball bearing throughout, thus reducing frictional losses to a minimum. All ball bearings are of the highest quality. The housing of this tool is made from an aluminum alloy, highly finished, and the tool is pleasing and sturdy in appearance.

A special care has been exercised in its design relative to that member which contain the nozzles, so as to permit of easy cleaning of dirt or any foreign matter which may become lodged in the nozzles. The lubrication of the tool is accomplished by having all bearings and gears in one housing, using an especial semi-liquid lubricant which is sufficient for from three to six months' use, depending upon the total actual working time. This drill has a capacity of 5/16 in. in steel and ⅜ in. in wood, and is equipped with Jacobs chuck, and, weighs 6 lbs. complete. It is manufactured by The Turbine Air Tool Co., Cleveland, Ohio.

PNEUMATIC DRIVING CLUTCH

A pneumatically operated clutch has recently been placed on the market. The clutch consists of two discs with cork-covered conical faces on the periphery. The discs are driven by pins to a triangular plate which forms part of the hub. When operating the clutches the air passes through the hubs between the discs while the hub is revolving, the discs being fastened together at the periphery with a flexible, air tight connection. When the air comes through the inlet it is forced between the discs, spreading them apart, this action forcing the conical friction surfaces of the discs into contact with the outer case, the latter being carried on a ball bearing quill. When released the discs are brought back to normal position by means of springs. These clutches are particularly adapted to fields where clutches of large horse power are required, or where control is desired at a distance. Low pressure air is all that is necessary, the amount being one to three pounds. End thrust on bearings is eliminated owing to the opposed nature of the drive. To maintain constant contact a continuous flow of air is allowed to go into the clutch. One pound of air in a 30 in. clutch gives a spreading power of about 1,400 lbs. These clutches are manufactured by the Rogers Foundry and Manufacturing Co., Joplin, Mo.

IMPROVED PNEUMATIC GRINDER

An improved pneumatically operated portable grinder has recently been offered to the trade. When used in connection with a wire brush an air motor is required to deliver continuous service, and therefore the bearings are more efficiently lubricated, so that an oil separator has been incorporated in the grinder. This improvement enables continuous service for 28 hours or even longer without replenishing the supply of lubricant. The application of a brush to this particular grinder makes this equipment serviceable for such work as removing rust, paint and scale from steel and iron surfaces. The brush consists of ⅛ inch steel back plate fixed so as to better retain the wires, and the other ⅛ front plate having a series of slots through which the wire extends. These wires are grouped in 30 renewable units of heat-treated crucible steel. The shell of the oil separator revolves around the vent tube and the oil laden air feeding the motor passes through the holes of the shell. The oil is separated from the air by means of centrifugal action and returns back into the mechanism of the grinder. These tools are manufactured by the Chicago Pneumatic Tool Co., New York.

PORTABLE OIL-BURNING FURNACE

A special forging and welding furnace that may be transported from place to place in the shop for forging and rivet-heating has recently been placed on the market. The furnace is substantially and firmly made, the frame work being of angle iron and sheet steel. The work opening is 6in. wide, 3in. high at the edges and 4in. high in the centre. The fire chamber is 9in. wide, 7in. deep and 5¾ in. from the butt to the back. The oil tank which is placed within the frame and beneath the fire chamber will stand the pressure of 100 lbs. per square inch. It has a capacity of 14 gal. of fuel, sufficient for 10 hours of average operation. The tank has a 2in. air-tight filling opening and is likewise provided with a safety valve. The fire-clay shapes are simply constructed and may be quickly renewed. Air pressure is obtained from the ordinary shop line. The shipping weight of the furnace is 600 lbs. These furnaces are manufactured by the Wayne Oil Tank & Pump Company, Fort Wayne, Ind.

B. & S. THICKNESS GAUGE

The Brown and Sharpe Thickness Gauge No. 646, affords a relatively inexpensive precision tool of this type, which it is claimed, fills an important need. It contains six blades: .0015 in., .002 in., .003 in., .004 in., .006 in. and .015 in. in thickness, which can be used together or singly and give a variety of measurements up to .0315 in. These sizes have been selected by the makers as ones most frequently used, and to give a complete range of measurement. These blades are not rolled to size, but

New Thickness Gauge

are ground to the correct thickness. The gauge has been designed with an eyelet in one end so that it can be carried on a ring or hung up. It is especially useful to the motor mechanic and to automobile drivers, for it answers the requirements in many places around a

Modern Hoisting Efficiency

IN THE development of equipment making for economy and efficiency in the modern industrial plant, hoisting and conveying equipment occupies an important place. Since production costs must be kept at a minimum in order to meet competitive conditions, operations must be carried on with the greatest possible economy. The day is passing when the shifting of a machine or the transfer of material or the routing of work calls for the attention of more men than those immediately concerned in that particular operation.

The useful chain block, the pneumatic hoist, the portable floor crane, the heavy travelling crane, the industrial or freight elevator, all figure prominently in the scheme of industrial purposes, and to-day it is a most exceptional case when they are not employed as essentials in some shape or form.

Imagine a three-floor furniture factory without a hoist or elevator of any description, conveying by hand the different pieces of work by stairway from floor to floor. Consider the handicap to continuous, concentrated labor in such an establishment to say nothing of cost of production as compared with a plant where shifting and other routing processes are done by machinery. Consider, on the other hand, a large leather manufactory, not only with ten or twelve elevators, and employing hoisting equipment for the handling of large quantities of hides in various tanning processes, and thus eliminating much manual work. Consider these two actual cases and you have the difference between modern efficiency and effete conservatism.

Problems of Malingering

IN THEIR attempts to reduce malingering to a minimum under the Workmen's Compensation law, manufacturers have been confronted by some interesting facts. In 1920, the scale of compensation was increased from 55 to 66 2-3 per cent. There was an increase in the number of accidents during the first year under this scale, of 10.592, though the number of workmen employed was practically the same, and the amount of compensation awarded increased from 4 1-4 millions to 7 3-4 millions although 2 1-4 millions went to pay increases in respect of old cases. The startling increase, it is held, is undoubtedly due, in part, to malingering. The figures for 1921 show that while there was a decrease of 17 per cent. in the number of accidents, the awards had actually increased by about $100,000. It is evident, therefore, that workmen did not return to work as promptly as when the scale was 55 per cent. This fact is important when it is considered that 50 per cent. of the cases were one to two weeks cases and that the cost of medical aid was, in a great many cases, more than the actual compensation.

It is not surprising therefore to find that manufacturers are inclined to express themselves as favorable to a three-day absolute rather than a seven-day non-absolute waiting period, and that, further, they favor a contribution by employees to the cost of medical aid. A feeling on the part of the employee that he has some responsibility in the matter, except in most extreme cases, would seem helpful in the malingering problem.

When Stability is Necessary

TWIST drill production, of late, has been confronted by somewhat the same condition as that affecting the machine tool industry—a capacity that, for the time being, seemed beyond the requirements of the market, especially since that market came out of the war with large stocks on hand. In this case, however, these have become fairly well absorbed, but the change from a buyer's to a seller's market brought developments not altogether desirable in the viewpoint of the manufacturer desiring stability.

Discounts, in some cases, have been such as to bring the selling price perilously near, if not actually below, the cost of production at the present time. In fact a 70 per cent. discount on a half-inch $2.20 carbon drill is lower than the pre-war figure at 65 per cent. On high speed drills, a discount of 60 and 10 at the present time compares with 40 and 10 before the war when material and labor were both available at lower prices.

Naturally, the price war, if such it may be termed, was chiefly effective where most business seemed to offer, that is in the Windsor and Walkerville districts, the buying headquarters of a large section of the motor car industry, where to-day the competition is still at its keenest, confined as it is, largely, to two local concerns.

Then, on bit stock goods, sold largely through the hardware dealers throughout the country, the same tendency manifested itself, but a firming process is evidently developing here. Where a discount of 65 and 10 was the rule a recent reduction to 60 and 5 was introduced, with prospect of general recognition.

Even in carbon and high speed drills, the figures given above are not representative, and this but illustrates the condition of the market. On carbon drills a discount of 65 and 10 is quoted in some quarters, as against 70, and on high speed a discount of 50 as against 60 and 10. One manufacturer, asked for his fair market price, preferred to withhold it, considering the problem beyond any positive assertion.

Conditions on taps and dies are better. Here some stability has developed, and fairly good business is being done. There is quite a demand for hobs and other small tools for the motor car industry. It is gratifying to note a movement to get away from production on a below cost basis. The ship of industry can best make headway on an even keel. Stability is the thing and a better general outlook, rather than local possibilities, will undoubtedly bring the remedy.

Situation Producing Uncertain Market Condition

Advices From Iron and Steel Centres Say Minimum Prices Only Nominal—Blue Annealed Sheets $2 a Ton and Black and Galvanized $3 a Ton Higher—Steel Production Average Lower—Pig Iron Up $2.

STRUCTURAL MATERIAL STILL IN GOOD DEMAND

ANY LIKELIHOOD that the year's output of pig iron and steel would reach exceptionally high levels and thereby strengthen the feeling that industrial prosperity was "just around the corner," is meeting with discouragement. The shopmen's strike in the United States has already handicapped delivery of coal from non-union fields and metal production is already from 5 to 10 per cent. below the highest rate. A coal shortage in Canada, so far as industrial requirements are concerned, seems difficult of definite estimate. Only 16,100 tons entered Toronto in July this year as compared with 118,000 in July, 1921. The probability of Welsh coal getting beyond Montreal is more or less remote, unless the problem produces an organization that will work out a temporary rationing scheme. Manufacturers are considering the best step to be taken, but on the other hand, enquiries indicate that the number of firms having good supplies on hand as the result of foresight, is quite large. As conditions grow more serious in the United States, Government control of the situation is more in evidence. The Interstate Commerce Commission has introduced a priority system and as iron and steel producers are far down in the list, there is likely to be a considerable accumulation of orders against the day of settlement. An embargo on coal shipments to Canada seems almost unnecessary as there is very little coal moving.

Despatches from Pittsburg state that shortage of coke supplies is the big difficulty since many of the mills have enough coal to roll all the steel they can produce. Here again, the shutting down of furnaces seems to be anything but general as there are better supplies of coal in some districts than in others. Producers and buyers are taking the situation calmly and outside of some pressure on mills for specific delivery on contracts, there is no excitement.

Business men declare that the strike trouble is likely to cause a period of caution, based on necessity for economical production and reasonable prices. In fact, it is held in some quarters that the present disturbance will hasten reaction due to the tendency to do too much building all at once. The steel market, however, seems strong. Mills are well sold up. Minimum prices are being adjusted temporarily. In sheets, while old prices are nominally in effect with some mills, buying is being done at higher levels, say $2 a ton higher on blue annealed, and $3 a ton higher on black and galvanized.

Advance in Pig Iron

The market generally seems to be developing that aspect when nothing seems sure and every phase of the situation must be considered on its merits as it appears. Canadian prices reflect the situation. An advance of $2 a ton on pig iron only serves to illustrate problems of production. In one instance a Canadian firm has shut down its two pig iron furnaces. One was being relined and it was expected would again be placed in operation when completed, but now the coal shortage has necessitated the inactivity of both. There are, however, large supplies of pig on hand. Specific dates are now being observed and as to new business it is doubtful if anything is being booked for later than September.

July, on the whole, has been a fair month in Canadian business. A slump in the two vacation months is generally regarded as a matter of course, but this year it has been slow in coming. June was a good month in many respects—so good in fact that a serious reaction was looked for in July, but it did not develop seriously. Large tonnages in structural material were called for and producers say that this movement shows little abatement.

Montreal reports that July business will show a very good average, with general demand much better than it was one year ago. In addition to the advance of $2 in pig iron, there has been a boost of 10 cents in steel at the mills. There is also a firming tendency in non-ferrous metals. Stocks are very low in standard sizes and gauges of galvanized sheets, and it is predicted that the demand in this department is something more than seasonal. So far as machine tools are concerned, the situation appears to be brightening and dealers are optimistic as to the Fall outlook. Sales policies are aggressive, for enquiries encourage the feeling that business is approaching the stage where it is more susceptible to actual development. There have been no price changes, the general feeling being that they are now on an attractive basis.

Toronto

August 2 1922

GENERAL satisfaction with July business as compared with that of June marks the half year's turn in this market. Good tonnages of structural materials are still being received, foundry business has improved, and there is a distinctly better tone throughout the iron and steel business—but the cloud that threatens is the coal and rail strike. Manufacturers who are well stocked are beginning to watch the effects of daily consumption, while those who are not well supplied are considering ways and means by which they may carry on. The extensive use of electricity is an important factor when labor troubles develop in the summer months; had it been winter, with its necessity for warmth, the situation by this time might have been serious indeed. In fact, a more or less prominent labor man expresses the opinion that had the strike been called in winter months, the strikers would have won an easy victory. Just what provision the unions would count upon by which to supply members with fuel, does not appear. The news of most importance is that which promises an early settlement of the present trouble. In the meantime, Canadian industry is carrying on.

Scrap metal markets are reported as being decidedly lethargic. There have been no price changes of any importance during the past week. One dealer sized up the situation as follows: "Consumers seem of the opinion that prices will shortly show a reduction, while, on the other hand, dealers declare that, all things considered, present rates are about right and that they can see no immediate reason for expecting reductions." In fact, should present labor disturbances develop seriously and supplies of material dwindle, the price movement, if any, will hardly be downward. Current prices follow:

Copper, light ... ... per 100 lbs.	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper Wire	11 00
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings ...	4 85
Light brass	3 50
Medium brass ...	4 50
Scrap zinc	4 00
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton ...	9 00
Heavy melting steel ...	11 00
Axles (wrought iron) ...	16 00
Rails (scrap)	11 00
Malleable	11 00
No. 1 machine cast iron ...	16 00
Pipe, wrought ...	6 00
Car wheel	16 00
Steel axles	15 00

Iron and steel bar prices in which department there was an advance of 10 cents three weeks ago have now become stabilized. Some price-cutting was reported from the East, but this has evidently been eliminated and the raise now has general application. Otherwise prices are stationary, and reflect none of the disquieting or uncertain tendencies reported from American markets. Very marked changes are reported to be developing in the sheet

market. Reports from Pittsburg show advances of $2 a ton on blue annealed and $3 on black and galvanized. For some time the demand has found a short supply in this department and now it appears an advance will be in order.

Iron bars	3 15 to 3 25
Steel bars	3 15 to 3 25
Reinforcing bars	3 15 to 3 25
Steel hoops	4 00
Tire steel	3 15
Spring steel	7 00
Band steel, No. 10 gauge and 3-16 in base	3 65 to 3 75
Small shapes	3 25
Sheets, black, No. 28	5 25
Sheets, blue ann., No. 10	4 25
Canada plates, dull, 52 sheets	5 25
Canada plates, all bright	5 25
Galvanized Sheets, No. 28	6 00
	6 35

In non-ferrous markets, the condition exists of a slack demand and a trend toward decidedly firmer prices. Activity in sheet lead is reported with prices generally unchanged. Tin is also meeting with some demand, and is now quoted at $36.25, while in other departments slight advances are scored. It is a difficult market to consider except from day to day as Canadian trend almost entirely reflects that on the American side, where at the present time the markets are subject to quickly changing conditions. Prices follow:

Lake copper	17 25
Electrolytic copper	17 25
Castings, copper	17 00
Tin	36 25
Spelter	7 50
Lead	7 00
Antimony	7 40
Aluminum	21 00

Machine tool markets report little improvement. Some sales are being made and enquiries are good. September it is felt, should see a better demand. Suplies are keeping up and tap and die manufacturers say that their market is showing quite a nice disposition toward buying. In drills and reamers, certain sections of the country are passing through a period of price adjustment, which has taken on something of the aspects of a price-cutting campaign, regardless of cost. It is remarkable that in a locality where business should be on a fairly stable basis, competition has developed very keenly—so keenly in fact that some manufacturers are remaining away until the situation shows some return to reasonable prices.

Although supplies are low, turpentine has again registered an advance of 10 cents—$1.65 to $1.75 per gallon in barrel lots.

Montreal

August 2nd.

FIGURES for the month of July indicate that about the same amount of business was handled as in June, which latter month was the best so far this year. During the past week the volume offered has not been large, but as the first two weeks of the month were exceptionally good the average for the month is good. Prices of steel at the mills have advanced another ten cents this week. The jobbers have not altered their prices as yet. Pig iron has advanced two dollars a ton. Business in steel products is much better than it was this time last year, but is below the figures of some weeks ago. Consumers of pig iron are rather well covered and buying is slowing up. Machine tools are still very dull. Shop supplies are moving satisfactorily. The non-ferrous metals are somewhat stiffer in price, the demand remaining about the same as last week. The scrap metal market continues dull.

Iron and steel:—The demand for galvanized sheets continues to be slightly in excess of the supply. Shipments arriving for local jobbers do not often find their way into the warehouses. For some time past, warehouses have carried no stocks of standard sizes and gauges except in a few rare instances. Black and blue annealed sheets are also enjoying a good demand. The activity is seasonal, but this year it is believed that sheets will be active right up until the close of navigation. Structural steel, merchant bars, and a large range of steel products are moving very well indeed, considering the fact that this is the month that is generally accepted as being dull, owing to the general disorganization due to the holiday season. Plates are very dull locally. The coal and rail strikes are commencing to have a direct influence on local trading. The mills advanced their price of steel ten cents per hundred pounds base during the week. Large consumers are quoted $2.50, and jobbers $2.70 base per hundred pounds. The jobbers are still quoting from $3.15 to $3.25 to the consumer, the larger orders getting the lower figure. The C. P. R. recently purchased a considerable tonnage of rails, and it was thought that the national system would also come into the market. This conjecture proved an error and it is now thought that nothing will be done till the directorate is appointed. The supply of steel locally has been sufficient to take care of all demands, but the future is viewed with more or less apprehension, as it is not known just to what extent the strike situation will influence supplies of raw and finished material. Local quotations are as follows:

Iron bars	3 15 to 3 25
Steel bars	3 15 to 3 25
Reinforcing bars	3 15 to 3 25
Steel hoops	4 00
Tire steel	3 15 to 3 25
Spring steel	6 00
Band steel, No. 10 gauge and 3-16" base	3 25
Small shapes	3 00

Pig Iron:—An increase of two dollars a ton has been announced in the case of both Canadian and imported pig iron. No. 1 Canadian iron is quoted at $33.80 a ton on track in car lots, while Summerlee iron is quoted at about thirty-two dollars on docks. To this figure there must be added wharfage and cartage, or rail haul if such is necessitated. In a great many instances the figure for Summerlee varies from the quotation on the Canadian by only a few cents. Foundries have covered their requirements for the next few months and the demand is falling off somewhat. The strike situation has a very direct bearing on this market and before the close of navigation there is a possibility of many peculiar situations developing. The foundries are increasing their daily melts slowly but surely, and this increased consumption will bring them into the market in the course of a couple of months.

Non-ferrous Metals:—Quotations on copper remain steady but from London there comes a report that tin is advancing rapidly. The local quotation on tin jumped a cent and a quarter during the week. Spelter, influenced by conditions in the United States, is up a quarter of a cent a pound. Lead stiffened a little during the week. Antimony remained firm at six and a half cents. Aluminum eased off a cent during the last few days. The local demand is much the same as last week, being composed mostly of small lots from points widely scattered over the province. The local quotations are as follows:—

Lake Copper	17 75
Electrolytic Copper	17 50
Castings, Copper	17 25
Tin	36 25
Lead	7 00
Spelter	8 25
Antimony	6 50
Aluminum	22 00

Scrap Metals:—Another quiet week has been noted in the scrap metal market. The local demand continues light. Some orders have been received from outside points. Local dealers are not stocking up to any extent, until there appears a better prospect of business. The local quotations are:

Copper, light per 100 lbs.	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper Wire	11 00
No. 1 compositon	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 00
Light brass	4 00
Medium brass	5 50
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton.	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	20 00
Pipe, wrought	7 00

Machine Tools:—No change is noted in the demand for machine tools. Inquiries continue to come in, but there is little actual business moving. For some months past, the sales have been only small tools and these in lots of one and two. In many ways the situation appears to be brightening, and dealers feel optimistic, stating that they expect a better demand in the Fall. In the meantime, sales are aggressively sought. There is no attempt at price cutting, and the turning in of used tools is discouraged. There is a small demand for used equipment.

Machine Shop Supplies:—The supply business has dropped off a little but there is still a fair volume of business passing. Repair and jobbing shops are rather busy and contribute largely to the business moving. The railways are buying only in small quantities for im-

mediate use. Some of the larger local manufacturing plants are closed and thus the business that they ordinarily would create, is absent. Prices are rather stable and little changes are noted from week to week.

Pittsburg

August 2, 1922

PRODUCTION of pig iron and steel has continued to decline, and the rate of output is now between 5 and 10 per cent. below the highest rate, which was attained late in June. There had been a rapid increase in the rate of production in the first three months of the year, and a small increase in the next three months, after the coal strike began. The restriction now is due chiefly to poor functioning of railroads, on account of the shopmen's strike begun July 1. The roads serving non-union coal fields in West Virginia and Kentucky were, however, overburdened, there being extra production induced by the failure of supplies from union fields, and the great decrease in production in the Connellsville region, where there have been many sympathetic strikes. In particular, by-product coke plants were depending largely upon West Virginia and Kentucky coal.

Government Steps

The Government has taken charge of coal distribution and coal prices, a general priority system being announced July 25 by the Interstate Commerce Commission, while July 28, H. B. Spencer was appointed coal administrator. However, in this district the Pennsylvania Railroad and the Pittsburgh & Lake Erie have announced that as they are functioning 100 per cent. they have no occasion to observe the general priority and will make no change in the operations unless specifically instructed from Washington. Where the priority system has to be observed iron and steel producers and consumers are unlikely to get any coal, as naturally they are far down in the list.

Set prices, at something like a moderate level, say $3.50 for mine-run, are expected to be enforced, and in the last three days of last week the local coal market gradually lost its activity, consumers deciding to hold off for lower prices. Connellsville steam coal had reached a firm level of $8.50 but declined to $7.50 by Saturday. Connellsville coke, which is a rarity and has scarcely been bought at all except by foundries, advanced to $14 for furnace and $15 for foundry, but lower prices are now expected.

Operations in the iron and steel industry are affected chiefly by coke supplies, as steel mills seem to have enough coal to make and roll all the steel they can produce, once they have the pig iron. As to coke, the change is chiefly in by-product production. Some by-product plants have had their coal receipts reduced much more than others, while some have stocks, say enough to last 30 days more without any fresh receipts. Accordingly, the banking and blowing out of blast furnaces has been spotty, eastern Pennsylvania and the valleys being conspicuous, while the Buffalo district is probably next in line for a great decrease in furnace operations. Thus far, the Pittsburgh district seems to have gotten along rather well.

Steel Market Quiet

Unlike the condition in 1920, when a slight restriction in steel production, causing the industry to run at about 80 per cent. of rated capacity, threw buyers of steel into a panic and made them bid altogether fancy prices for steel, although when the excitement was over some of them had considerable stocks, the present restriction in production and shipments is taken very calmly. Perhaps the general run of steel buyers have fair sized stocks, or perhaps it is simply a case of their feeling they cannot afford to bid extra prices, on account of prices at which they are selling their products. Many buyers are exerting pressure on mills, trying to get better deliveries on orders they have already placed, but that is different from going out into the market and making fresh purchases at premium prices. There is some of this, causing delivery premiums to be stiffer, but the tonnage involved is practically inconsequential.

As to the more distant future of the steel market, and of business conditions generally, the present troubles due to the railroad and coal strikes unquestionably have a bad influence. The point is being commented on generally in business circles that the present disturbance is likely to have a bad effect, tending to slow down business and make men cautious. In 1920 rising prices were wrongly interpreted as foreshadowing longer continued and greater "prosperity" but all business men afterwards recognized their mistake. The philosophy of business is that for real prosperity there must be economical production and reasonable prices and anything that puts prices up or causes industry to operate at a disadvantage, is unfavorable. It is plain that commodity prices generally are trending upward, on account of these strikes and the enormous amount of building now going on. The country is trying to do too much building all at once. Accordingly, it is feared that some time in the not distant future there will be a reaction.

Great Strength

Whatever the prospects for the future, the steel market, on the surface at least, presents an appearance of great strength. It is very difficult to buy any steel for prompt shipment, as mills in general are well sold up, and the period for which a mill is sold up must be estimated longer than 30 days ago, because production is not going to be as heavy for a time as was expected. For later delivery it is also difficult to buy, partly because on general principles mills do not want to sell so far ahead, and partly because they have not unlimited confidence in buyers' estimates as to what they will need. Requirement or option contracts are particularly objectionable to mills, but specific orders against construction work, when the mill is satisfied the construction job will go through, are acceptable.

The 1.60c minimum on bars, shapes and plates has practically disappeared, even on the most attractive orders for delivery at mill convenience, 1.70c being now the minimum, while that is possible only on late deliveries, large tonnages and desirable specifications. For anything like nearby delivery the price may be 1.80c to 2.00c, depending on various circumstances.

In sheets 2.40c on blue annealed, 3.15c on black and 4.15c on galvanized are still nominally in effect with some mills, for indefinite delivery, but as a rule buying, if done at all, is at higher prices, at least $2 a ton higher on blue annealed and $3 a ton higher on black and galvanized. There is not much buying, the chief interest of consumers being in deliveries against orders already placed.

Inquiry for pig iron is extremely light. Forced buying of any magnitude would send prices up sharply, as there is little iron to be picked up. Evidently consumers are not in a position to pay fancy prices and prefer to get along as best they can with iron in stock or iron due on previous purchases. Some foundries are found to have considerable stocks, which was hardly to be expected with the limited production of the past three months, and there are stocks at a few furnaces. Last sales were at $25 for Bessemer, $24 for basic, $25 for foundry and $27 for malleable, f.o.b. valley furnaces, but it does not follow that these prices could be duplicated on fresh purchases. On the other hand no one can be sure that if any large tonnage were forced on the market it would bring prices as high as these. In other words, no one can be sure of anything and developments are being awaited.

Strike of railway shopmen has been averted for the present. The dispute will be considered by a Board of Conciliation on which Isaac Pitblado, K.C., Winnipeg, will represent the railways and James Simpson, Toronto, the shopmen.

Montreal carpenters and joiners engaged in the repair and alteration of ships in port, have unanimously endorsed the report of a board of arbitration which sat recently to consider differences as to wages which arose last April between the local and a number of navigation companies, represented by the Shipping Federation of Canada, Inc. The scale of wages was fixed by the board at 55 cents per hour per day, and 65 cents at night. This is five cents per hour above the rate which went into force April 22 last, but considerably under the scale asked for by the men at that time.

News From the Industrial Field

Walker Twist Drill Co., Walkerville, have ceased operations for a two weeks' vacation period.

Frederick J. Clark, Toronto, has been appointed Industrial Commissioner, Niagara Falls, Ont., at a salary of $3,500 and expenses.

D. B. McCoy, formerly sales manager at Vancouver, B. C., of Steel Company of Canada, was recently transferred to the Toronto office, Bank of Hamilton building, as manager.

Canada Machinery Corporation, Galt, report continued improvement in business especially as regards wood working machinery. The staff is being increased gradually.

Reports from Galt indicate that the coal situation there is not without some serious aspects. Industries that have been fairly busy have fast dwindling supplies, while others whose operations have been curtailed have considerable quantities. Manufacturers generally made provisions against shortage but the strike is more protracted than was expected.

A despatch from Peterboro states that manufacturers in that city are so aroused over the continued shortage of power that they have given consideration to the feasibility of the municipality taking over the control of the water powers. They charge discrimination on the part of hydro by serving new and seasonal canning concerns, while the old customers go begging, and they charge the hydro with over selling.

Western demand is reported by manufacturers as showing greater activity, a reflection of the encouraging crop outlook. Tap and die manufacturers say they have been receiving large volume of business from that quarter and well pump makers are shipping increasing quantities. One of these concerns received an order recently for a carload of small pumps: nothing exceptional in normal times, but indicating a much better buying feeling than has been for some time.

Windsor.—Dodge Brothers Motor Co., Ltd., of Canada, has purchased seven and one-half acres in this city as a plant site, it has become known through registration made at the Sandwich registry office. The land purchased is triangular in shape and is bounded by the Canadian Pacific Railway, Jeanette Avenue and Pelessier Street. It has 1,934 feet of frontage on the Canadian Pacific Railway and is about three miles from the water front. No plans have been made for the erection of buildings, however.

Indicative of the coal shortage is the fact that only 16,100 tons entered Toronto in July this year, as against 118,000 in July, 1921. No anthracite entered Toronto since early June. As regards coal from Wales, an authority declares that it would take somewhere around 1000 boats to supply a week's shortage on the continent.

Kingston.—Another indication that business conditions are returning to a normal and prosperous state is shown by a betterment in local industries. The Frontenac Floor and Wall Tile company, started as a small concern, is employing sixty hands and expects to need more. Two new kilns have recently been installed for the manufacture of wall tile and will soon be in full operation.

The John T. Hepburn Co., Toronto, have just completed some Maclean underfeed stokers for the Farmers Dairy, Toronto. They have also finished a big derrick with a 70 foot steel boom for Kilmer & Barber, Toronto, this being the largest they have ever made. They are at present making some new hand pressed brick machines, and report their steam pump line as very good. A few days ago they shipped to the Queen's University, Kingston, a 10 x 6 x 12 outside center packed high pressure pump, and say that things looked somewhat brighter all round.

Montreal.—The United States Government announces through the office of the Quartermaster General of the American Army at Washington, D.C., that Charles S. Gerth, of Gerth's Realty Co., expert international auctioneers and specialists for the liquidation of industrial properties, will sell at auction on Tuesday, September 5th, the Peter Lyall Construction Company plant at Longue Pointe, Montreal, and the Munitions and Machinery, Limited, plant in the City of Lachine. The conditions and terms under which the sale has been ordered should prove of unusual interest to either American or Canadian industrial concerns contemplating expansion. The bidder for the Peter Lyall plant which is successful in acquiring same, will find it only necessary to pay 20 per cent. at time of sale and the balance in 5 years at 5 per cent. interest. The purchaser of the Munitions and Machinery, Ltd., plant will be required to pay down 30 per cent. cash and the balance in two years at 5 per cent. interest. The plants are to be sold "as is" without any guarantee as to condition. Prospective purchasers will be given ample assistance in visiting and investigating the general conditions of the plant both as to buildings and equipment. A prospectus containing pictures and complete details of both plants is being prepared. The hour of the sale of Peter Lyall plant will be 10 o'clock in the morning and the sale of the Munitions and Machinery, Ltd., plant will be 3 o'clock in the afternoon of Tuesday, September 5th.

Peterboro.—The Manufacturers' Association have requested Mayor Taylor to call a meeting of coal dealers to confer on the local situation. The importation of coal from Great Britain was urged as one solution.

Montreal.—It is understood that the Montreal harbour commissioners are ready to build a modern pier at the Peter Lyall, Longue Pointe, plant with a guarantee that the wharfage will show a profit of 7 per cent. of the cost, annually for at least ten years. In the event of a pier being built and the manufacturer's business falling short this amount, he would have to make the deficit good. On the other hand, however, he would not be called upon to spend any money for the construction of the pier.

Kingston.—General outlook for industrial activities in Kingston is very bright at the present time. Not only have two or three very satisfactory industries commenced operations here, but the prospects for building operations on a large scale in the very near future are indeed encouraging. Following on this comes the announcement that the Baldwin Locomotive Company is winding up the details of purchasing the Canadian Locomotive Company's plant here. The various municipal boards and boosting societies are becoming more convinced daily that the city of Kingston is on the eve of a very prosperous era.

Montreal.—A field house is to be built for McGill University adjoining the Molson Stadium, which will cost approximately $32.000 when completed and equipped. The contract for the erection has been let to the firm of D. G. Loomis & Sons. Construction will start soon and the building will be completed and equipped early in the autumn. Tenders will also be asked for the new McGill Gymnasium on or about August 25th. It is understood that the plans will be completed about August 5th. Tenders for the new pathological building which is to be built between the Royal Victoria Hospital and the Molson stadium will also be asked for during August. The foundations for this building are completed. In addition the foundation for the new mining-geological building will be started this autumn, but the erection will not be commenced until early in 1923. The extension to the power station will be undertaken as soon as the new buildings are sufficiently advanced to demand more power than produced at present.

Kingston.—Elmer Davis, president Kingston Board of Trade and head of A. Davis & Son tanning company here, has just returned from a trip through western Canada to Winnipeg, Calgary and Edmonton. He is firmly convinced that the tide has definitely turned for the better in the business world, and that we are entering upon an era of sound, solid business prosperity. In an interview Mr. Davis said:

"I think that the depression is over without question, and that business conditions from now on in this country will steadily improve just as they are steadily improving in the United States in spite of the coal and rail strikes. This year promises to give us the best crop Ontario has ever had, while the crop prospects in the West are fair, to say the least. This means the creation of millions of dollars of new wealth. Wherever I went I found changed sentiment and a most encouraging note of optimism, business men and leading financial interests all agreeing that we had turned the corner and that we could look ahead with much more confidence and hope."

EXPLAINS TAX INCREASE

Ottawa.—The Minister of Customs and Excise, Hon. Jacques Bureau, explains the increased taxes which come into effect August 1, as follows:

"The increased stamp tax on bills of exchange, bank advances, overdrafts, cheques, sales and transfers of stocks and bonds, express money orders, travelers' cheques and post-office money orders, becomes effective on August 1 next.

"The tax on bills of exchange promissory notes and advances or overdrafts is payable at the rate of 2 cents for every $50 or fraction thereof.

"Cheques, money orders and travelers' cheques for amounts of $50 or under require a 2 cent stamp. If the amount for which they are issued exceeds $50 but does not exceed $5,000, a 2 cent stamp for every $50 or fraction thereof is required to be affixed thereto. Cheques, money orders and travelers' cheques which exceed $5,000 in amount require a $2 stamp.

"The tax is to be paid by means of excise tax stamps in preference to postage stamps, affixed to the face of the cheque or money order. Regulations have, however, been issued whereby the tax on cheques may be paid monthly in place of affixing such stamps to the individual cheques. Under these regulations the cheques are embossed with a stamp stating that the excise tax has been paid. Special licenses are issued by the Department of Customs and Excise to firms who desire to pay the tax monthly."

J. T. Hepburn of John T. Hepburn Co., Toronto, is at present in Scotland with his family on a pleasure trip. He has purchased a motor car over there, and is touring the country seeing the beauties of the old land.

RAILWAY SHOPS TO RUSH ROLLING STOCK FOR CROPS

Fort William.—Definite announcement is made that starting August 1, local shops of the Canadian Pacific Railway, which since the first of the year have been operating at part time only, will go on full time operation. The increase in operation is due to anticipation of the operation officials of the road, of the need for every available article of rolling stock to move the 1922 grain crop in the west.

Every effort is being made to have the million bushel capacity storage annex to elevator O,—N. M. Paterson and company, grain firm,—completed in time to handle 1922 grain. 1,600 piles have been driven for the foundation and in two weeks, work will have advanced to a stage ready for the pouring of concrete. The annex will comprise forty-three concrete bins, circular, and ninety feet high, giving elevator O a total capacity of 1,750,000 bushels. The work is being done by the Fegles Construction Company.

Fort William has three months' supply of coal stored for domestic, district and Manitoba use. There are 70,000 tons of nut and egg coal with no stove coal available. This time last year there were 80,000 tons of this class of fuel on hand. Soft coal is more plentiful, about 200,000 tons showing on the record of stocks, about equal to last year's figures. But no coal is arriving to replace the dwindling stocks. Only two cargoes have reached here so far this season. None is in sight. If mining is resumed it would probably be six weeks before coal could be available for western shipments. The situation seems to be that Fort William and the districts usually receiving supplies from this port, will be under fuel famine conditions at the worst and suffer a decided pinch by snow time at the best.

Both railroads here are beginning to run short. The Canadian Pacific has 60,000 tons and the Canadian National 10,000 tons. It is expected if an emergency arises both roads would commandeer the domestic stocks from dealers' yards here. They did so in a similar emergency during the war.

Coal prices were advanced here to-day, hard coal going from $18.50 to $19.50 per ton; the so-called pea coal moving up 50 cents from $13.50, and soft coal advanced $2 per ton.

Concrete work in the new two-millions-bushels-capacity annex to the Northwestern elevator here, is now practically finished, and the contractors, Barntt and McQueen, expect to have the house completed by September 15. The same company is also building a $1,500,000 addition to the Richardson elevator at Port Arthur, and expect to have it completed on September 15 also.

THAT the strike situation in the United States is reaching that stage when it is having serious significance from a national point of view is evident from the emergency order of the Interstate Commerce Commission establishing priorities in all railroad traffic and in fuel distribution. The order was effective last Tuesday at midnight. It recalls the war priorities of four years ago, but there is a difference in the present case which requires that, until the more essential consuming lines have been supplied, iron and steel and associated activities must wait for their supplies of fuel. It is stated that industrial supply in United States would be badly depleted within 30 days. Already the stoppage of shipments from steel mills is noticeable. There has been a slackening in the steel industry generally although it is reported that activities in the Pittsburgh district are keeping up well on a level with previous weeks. Food shipments are fully provided for.

While no such order has yet been issued in Canada, it is a fact that the railroads are cutting off many local trains in order to conserve coal supplies. In the steel and iron industry there is a tendency in a similar direction. Buyers are beginning to specify dates on their contracts and furnaces are adhering to the necessities of this development rather than to the consideration of tonnages from new sources. That is, their customers will receive prior service. It is a fact that Canadian railroads and industry generally have shown the benefit of experience by storing large quantities of steam coal, but of course there are cases where foresight was not brought into play, and there will be shortages. A thirty-day consumption on reserves would, however, reduce them to the danger point. One favorable factor is that a good many industries are operating below normal. Foundries and other plants working on material for the building trade, and thus fairly busy may be hard put to it for necessary fuel. It is likely that there may be co-operation among industries to help each other over their fuel difficulties.

There is a ready market for hand tools of all kinds in Belgium, according to a report from reliable trade sources.

A British oil company has been occupied during the last few years in completing one of the largest oil refineries in the world. This refinery occupies a site of about 650 acres near a British port, and it has involved the expenditure of about three million pounds. From the jetties where the tank steamers are unloaded pipe lines are laid down to eight tanks, which are capable of holding ten thousand tons of oil. Electrically-driven pumps are used to convey the oil from these tanks to storage tanks situated at the refinery about four miles away. The storage tanks have a total capacity of nearly twenty-one million gallons.

LARGE HERRINGBONE GEARS FOR DRIVE

The Hamilton Gear & Machine Co., Toronto, Canada, have just completed some large herringbone gears for the Dodge Mfg. Co. These gears were much larger than the usual run, and are to be used for the head drive on grain elevator legs. The largest gear of the pair was 45 in. diameter, 12 in. face, while the other was 12 in. diameter with a similar size face. Three sets were made.

This new style of drive will supersede the old style rope drive where the power was located at the bottom of elevator and transmitted by ropes and groove pulleys to the top of leg. The motor will now be located at head, and connected by herringbone gears and flexible coupling to the upper drum of bucket conveyor. This arrangement is said to be the newest and best method of driving grain elevator legs.

In addition to the above, the Hamilton Gear & Machine Co. are working on an order for double reduction truck axles for the Harmer Knowles Truck Co., Toronto, also making some large spur gears for the Goodyear Tire & Rubber Co., who are making some enlargements to one of their mill lines.

Montreal.—Mr. W. M. Brittain, general manager of the Import and Export Board of Trade of Baltimore, and Mr. John Baker, general foreign traffic manager of the same organization, visited Montreal, July 14th, as guests of Mr. P. Fennell general manager of the local harbour. These gentlemen showed great interest in the facilities of the local port.

Introducing

G. M. WILSON,

Superintendent Grand Trunk Motive Power Shops, Pointe St. Charles, Montreal.

BORN IN Belfast, Ireland, Mr. Wilson came to Canada at an early age. His taste for things mechanical was very pronounced, long before his school days were completed. Before entering actively into machine shop life, he was often found in the vicinity of repair shops. It is related that on one occasion he was lending a hand on a job of assembling a steam traction engine that had been undergoing repairs. Single handed he set the valves, and gave the engine a test run around the streets of Sarnia. Thus, his desire for motoring manifested itself before motors were commonly seen.

In 1889-90 Mr. Wilson was employed as a machinist with the St. Clair Tunnel Co. For a short time after this he was with the Jenks Shipbuilding Co. of Port Huron, Mich. In November, 1890, he entered the Grand Trunk Railway shops at Fort Gratiot, Mich., now known as North Port Huron. In these shops it was not long before he rose to be an expert machinist, and later was promoted to be machine shop foreman. In 1910, he was supervising the repairs and maintenance work on the three large car ferries running between Windsor and Detriot. In the late autumn he went to Ottawa to supervise the installation of the power plant and machinery of the Central Station and the Chateau Laurier Hotel. He spent two years in Ottawa, at the conclusion of which time he was appointed general foreman of the Toronto shops. In 1914 the position of general inspector fell to his lot, and in 1916 he was made assistant superintendent of the Point St. Charles G. T. R. motive power shops, Montreal. Upon the death of the superintendent in 1917 he was appointed superintendent, a position which he now holds.

Mr. Wilson is of a very genial disposition, and is interested in many lines of sport and recreation. Motoring gives him great pleasure, but he thinks that it is wonderful sport to land a fish. Lawn bowling has a place in his heart, and he is a great lover of football. He is an all-round sport but at the same time is always busy and takes great pleasure in his work. He has many outside connections, among which is the Canadian Railway Club, which organization recently elected him president.

Safety As An Efficiency Factor Demonstrated By Actor-Workmen

COMPARISON of present day safety methods, with those of an earlier period when responsibility for an accident had, like the vagrant, no permanent place of abode, was strikingly illustrated at Hamilton. The occasion was a meeting of the Implement and Vehicle Manufacturers Safety Association at the plant of the International Harvester Company.

The feature of an interesting program was the sketch: "Fixing the Responsibility for Accident," put on by the employees of the Steel Company of Canada, the International Harvester Co., and the Canadian Westinghouse Co., under the direction of Chas. E. Naphtale, Guelph. The men entered with particular zest into the presentation, and, their task was to present two sides of conditions applicable to daily experience, the realism of their acting was little short of perfection. The scene was that of a machine shop as operated under two widely different sets of safety regulations. William Light, a 20th century foreman, and Sam Stone, an old time foreman, were parts taken respectively by C. MacMenemy and A. Bramhall. Other characters were: George Brown, a guide boy for the employment office, a boy scout, by E. H. Hutchinson; Frank Cole, a bench worker in machine shop, by F. C. Reynolds; James Smith, a bench worker in machine shop, also a member of shop safety committee, by F. Watkinson; Leo Wise, a shop clerk, by Harold Bayley; Thomas White, operator of lathe No. 2 in the machine shop, by J. Slocomb; Harry James, a new employee, by E. T. Marks; Roy Lang, a new employee, by J. Smith; Charles Metz, a plant safety inspector, by J. Manewell; John Telford, supt. of machine shop, by L. L. McIntosh.

The playlet was a practical demonstration of the fact that in the so-called early days there was very little co-operation as between employer and employee toward safe working conditions. The foreman was very often a bulldozer who could see no merit in safety devices, who insisted that blame, if any, attached to the employee, and who drove his men, very often in picturesque language, to their duties amid surroundings that filled their lives with perpetual menace. There were few warning signs; guards to gears and other dangerous moving parts were conspicuous by their absence, and the penalty for accident was very often discharge, sans sympathy and sans compensation of any kind.

The players gradually worked up to the idea that protection pays and that sense of safety makes for efficiency. The contrast between the old and new was strikingly emphasized, greatly to the interest of the large attendance.

F. M. Morton, general superintendent of the International Harvester Company, presided. Prominent business men spoke of the importance of prevention work. A. H. Young, manager of industrial relations, International Harvester Company, Chicago, spoke on accident prevention. F. H. Wyse, of the Ontario

(Continued on page 59)

Babbitt as Material for Light and Heavy Bearings

Minimum Wear on Shaft Due to Composition of the Metal—Wearing Qualities of Good Babbitt—Oil Grooves Easily Cut—Various Grades for Different Uses—Method of Handling

By W. S. STANDIFORD

BABBITT as a material for light and heavy machine bearings does not seem to be used to the extent that it deserves; which is due, no doubt, to a lack of information as to its merits as a bearing metal and also to a prejudice against its use on various machines caused by ignorance in handling, as workmen can make the most expensive and high-grade babbitt appear worthless, in regard to the length of time a bearing lined with it will last and the trouble such a metal will make during the operation of machinery causes many factory owners to keep it out of their machine bearings.

Babbitt and brass are mostly used all over the civilized world as a bearing metal on various classes of machinery; both giving good results if they are of fine quality and well made, also suited to the weight of moving parts and plentifully supplied with grease or oil, care being taken not to let such bearings run dry. Brass is an excellent metal for journals and it gives fine results when constantly looked after. In these days of efficiency methods and rapidity of operations, the human element cannot entirely be ignored, and sooner or later, a factory's oiler will neglect to supply a brass bearing with oil when it needs it the most, a cut shaft and bearing resulting in a loss of time and money until the machine can be started again. The oiler in these cases mostly putting the blame upon dust working into a bearing and clogging it up, etc.; when in reality it was his own fault.

Brass and Babbitt

Brass has serious disadvantages when contrasted with babbitt ones which are as follows: owing to its composition, it is a metal that heats up rapidly if for any cause the flow of lubricant becomes irregular or intermittent; heating makes the brass expand rapidly, this in turn causes both shaft and bearing to be pressed together too tightly, the lubricating oil getting rubbed off their surfaces, a "frozen" bearing as it is technically termed, resulting. On the other hand, due to babbitt metal having altogether different characteristics from brass, it will stand more abuse (not that it is advisable to ill treat any machinery), and will run longer before a bearing cuts and seizes a shaft as compared to brass. Babbitt proves to be a very suitable composition for machinery bearings; its advantages in this respect are so great where smooth running machines are desired with the least wear on shafts, that this material gives the utmost satisfaction in factories when it is rightly looked after.

The fine wearing quality of babbitt is due to the fact that it has a more dense grain and also a greasier nature than brass. This gives to it great anti-frictional qualities, thus such a metal will run very much cooler under equal conditions than brass or any other metal. As babbitt can be melted in an iron ladle over any fire, great rapidity in replacing worn bearings in machinery breakdowns is a most desirable feature and also a money saver. In addition, oil grooves can be easily and quickly cut, or if preferred, cast ready made by the millwrights or machinists repair forces using asbestos cord. Uniform bearings are easily obtained in casting such bearings when care is observed in doing the work. Babbitt also has another valuable money-saving feature conferred by its low melting temperature, that allows the use of a portable forge for melting purposes, thus enabling all work to be done on the spot near the engines or other machines. This saves time by eliminating walking of the workers to and fro from the job, to the lowest possible extent.

This metal deadens noise, and last but not least, is cheaper than brass. There are a variety of different grades of babbitt on the market adapted to various machine requirements, such as high pressure and fast speed journals, medium pressure and medium speed and also low pressure and fast speed metals generally contain more tin and antimony with a small amount of copper; while the low pressure and medium speed metals usually have smaller quantities of tin and antimony and a large amount of lead. Tin, antimony and copper confer hardness to babbitts; so it will readily be seen that those who prefer to make their own formula for use in various classes of machinery bearings, can easily regulate its hardness to suit all requirements. There are many varieties of babbitts on the market so that any manufacturer who desires to purchase his own instead of having it mixed at his plant by the repair forces will have no difficulty in selecting a grade suitable for various machines; of course, taking into account the work they have to do as the conditions of working differ in various factories.

Most Suitable Grade

The methods of handling by workmen also have a great influence on the length of time bearings will last. None but high grade men should be employed to re-babbitt bearings. Personally, the writer thinks that, except for a few special cases, two kinds, one a lead-base alloy and the other a tin-base one are sufficient for the average class of machine journals, rolls being included in this list. But each metal ought to be of the highest possible grade that can be made. Rarely are bearings made entirely out of solid babbitt, except some very small ones including those made on die-casting machines, these latter are cast complete with oil grooves, etc. They need only to be turned and faced off before using. In general use, is used only as a lining in bearing shells of cast iron, malleable iron, brass and bronze.

Steel castings were found out by experience to be unsuitable for this purpose on account of warping tendencies when the casting strains are removed by machining. Cast iron shells on account of their cheapness and great strength, are most commonly used for stationary machines, also some malleable ones for the same purposes. The latter class gives fine results in machines which are subjected to heavy vibrations. The railroads generally make use of bronze shells so as to insure the completion of their runs and keep their time schedules as accurately as possible. Bronze or brass shells with a babbitt lining are also made use of extensively in the automobile trade. From the foregoing facts it will readily be seen the esteem in which this metal is held as a bearing material in different lines of manufacture. Owing to varying sets of working conditions encountered in shops and mills, it is necessary to use babbitts of such a composition as will prove suitable in order to have all machinery operate with the least amount of trouble.

Long Wearing Composition

Thus bearings carrying a heavy weight and rotating at high speed, need a metal whose ingredients are varied and also mixed in such proportions so as to obtain the best results. The formula given below is one that has been found out by long experience to give good satisfaction in journals supporting a weight of 2,000 lbs. and moving at a rate of 185 revs. per minute; it being one that enables machinery to continue in action for long periods of time assuming that lubrication is attended to regularly before bearings need replacing.

Formula For a Long Wearing Journal Babbitt

1,400 lbs. lead.
232 lbs. antimony.
165 lbs. alloy. (Tin and antimony mixture.)
5 lbs. bismuth.

In making up this mixture, there is needed a cast iron pot and also some ladles of various sizes; the latter should be of the self-skimming type having a

After All—It's Only Common Sense!

SOMEWHERE in every shop, there's bound to be a machine that—frankly speaking—should be scrapped. The floor space alone is too valuable for anything but a real producer—that's common sense.

We've met cases of this kind, we've listened to the old excuse "replacement too costly"; then we've shown them machines which straightway settled the argument. Often, we are asked how we can do it; and we reply, "Quality goods plus quick turnovers and small profits"—that's common sense, too.

If you're nursing along one of those "Cost-eaters" in your shop give us a chance to quote you. We'll make you feel glad you did and—after all, it's only common sense.

Our Monthly Machinery List is full of bargains. Shall we put you on our mailing list?

The A. R. Williams Machinery Co., Ltd.

64 Front St. W., Toronto

HALIFAX ST. JOHN MONTREAL WINNIPEG VANCOUVER

If its Machinery—Write "Williams"

welded bridge across their spouts so as to prevent dirt and dross from getting poured in with the babbitt. This iron bridge also prevents splashing and enables a good sized stream to be poured. A supply of mandrels, clamps, etc., will also be required by machinist's or millwright's repair forces. In making up the formula listed, experience shows that it is best to melt the tin and antimony alloy and bismuth in a crucible separately from the other ingredients; this is necessary because of the fact that it takes a greater degree of heat to melt them, than lead, as it is a matter of great importance in melting babbitt, (whether it is purchased ready for use or made on the premises) to avoid burning as the latter produces heavy shrinkage in all lining shells, besides reducing its antifrictional qualities.

Mixing the Metal

Such a mixture is also rendered dirty and softer in texture, causing all burnt bearings to wear out rapidly during the operation of machinery equipped with this metal. It is better to melt the lead components in an iron pot until it becomes fluid and then add the well-stirred antimony and bismuth mixture stirring frequently; after which, allow the alloy to remain upon the fire for awhile longer so as to make sure every ingredient is thoroughly melted and mixed. This ensures even wearing journals, the amount of time depending upon the bulk of metal melted. Powdered charcoal or else sawdust should be kept on its surface to prevent oxidation and a formation of dross by the action of the air.

(To be continued.)

SAFETY AN EFFICIENCY FACTOR

(Continued from page 57)

Safety League, outlined campaign plans, by which it is proposed to impress the importance of "safety first" not only upon the employees of industrial concerns, but also upon the public generally, young and old. One plan in view is to have motorists, during a safety week, pick up children or elders and demonstrate to them, for a short distance, how important it is that both pedestrian and motorist feel responsibility in taking every precaution possible.

R. B. Morley, general manager, Industrial Accident Prevention Association, also spoke. The outstanding idea was that one must be educated to think in terms of safety, and it was shown that all efforts in that direction had resulted in a lessening of the accident record.

FILMING ACETYLENE

Acetylene is one of the most wonderful substances in the world; and in order to make its marvels understood a British firm has produced a kinematograph film which reveals many of the processes adopted in compressing and using the gas. The compression is done in cylinders which contain a downy substance which is able to absorb an extraordinary amount of acetylene. In this form acetylene can be safely transported and employed in soldering, welding, and cutting metals and also in manufacture of jewelry.

INDUSTRIAL WELFARE IN SCOTLAND

When the construction of large factories was first begun, very little attention as a rule was paid to the health and comfort of the employees. The example given by Robert Owen about 100 years ago in Scotland was looked upon as the eccentricity of an enthusiast, but now it is generally recognized that on business as well as humane grounds the right policy is to give systematic care to the well-being of every class of worker. This phase of industrial enterprise has been very highly developed in England and Scotland; and the extent of its growth may be gauged from the fact that the Scottish Society of Welfare Supervisers has produced a national welfare magazine, consisting of forty pages, for distribution generally among those engaged in welfare work in Scotland. The aim of this magazine will be to co-ordinate as far as possible the various welfare activities carried out in Scotland.

NEW THINGS IN SHOP EQUIPMENT

FRICTION CLUTCH FOR GEAR-HEAD LATHES

A new design of friction clutch has recently been developed and placed on the market. Contrary to the usual design of expanding the ring on the one side, this clutch is constructed so that the ring is expanded on both sides. The expanders are in the centre of the clutch and are operated so as to produce pressure directly on the toggle lever. The levers are mounted on eccentric shafts so that uniform leverage can be maintained. These clutches have a larger diameter than the former models and are practically 50% wider on the base. They are manufactured by the Greaves-Klusman Tool Co., Cincinnati, Ohio.

SEMI-AUTOMATIC ARC WELDING SET

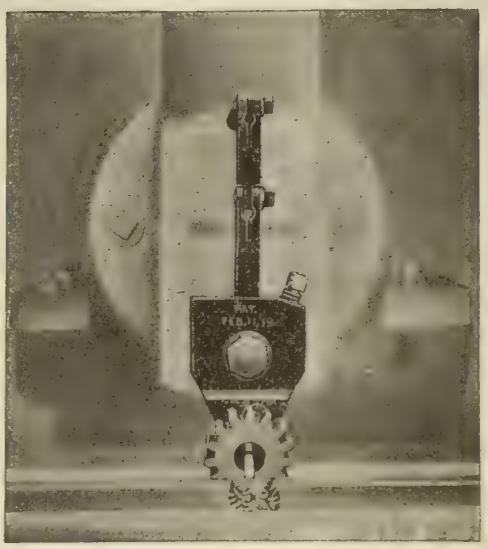
A portable semi-automatic electric arc welding set has recently been placed on the market. The set comprises complete semi-automatic equipment, all of which is mounted on a small truck that can be moved or pulled by hand or lifted by a crane. The welding equipment has an automatic welding head with controlled mechanism, and a stand for holding a reel of electrical wire. The reel carrier takes any size of reel up to 2½ feet in diameter. Owing to the continuous speed of electrode the time for welding operation is considerably reduced. The entire appliance weighs about 400 pounds and is manufactured by the General Electric Company, Schenectady, N.Y.

ELECTRIC HEATER FOR FORGING

A new type of Berwick two-path electric heater has recently been offered to the trade. The machine is especially designed for forging operations requiring the heating of the ends of bar stocks or points along the material. The heating operation is performed without burning or melting of the metal. These heaters are made on a unit principle with one, two or three electrodes, and may be supplied with a greater number if desired. The length of the heat can be varied from one to eight inches, or the machine can be adapted for heating lengths from three to eleven inches. With slight modifications in the machine these lengths may be increased to 18 inches. The lower or left hand electrode of each unit is stationary, while the upper or right hand electrode has a vertical movement operated by depression of the treadle which raises the electrode sufficiently to insert or remove the material. Each unit of the heater has two pairs of electrodes, insulated from the other. The right hand electrode is movable while the left hand electrode is stationary, so far as the vertical motion is concerned. Depression of the foot pedal causes rotation of the shafts which raises the shaft carrying the electrode. These heaters are manufactured by the American Car and Foundry Company, New York.

SLOTTING ATTACHMENT FOR SHAPERS

A slotting attachment for shapers is adaptable to production work in the tool room or machine shop work on intricate jobs. It is bolted to the clapper in



Moore slotting attachment for shapers.

place of the tool post and can be applied easily and as quickly as changing a tool. For shaping on jigs, gauges, dies, key ways slotting etc., it soon pays for itself. Made by The H. A. Moore Company, Rochester, N. Y.

PORTABLE PNEUMATIC DRILL

A new type of portable pneumatic drill has been added to the Thor line, and will be marketed under the name of "Pigmy." The drill has a pistol-grip handle with the control valve within easy reach. The machine is light in weight and non-reversible. These drills are made in three sizes, smallest taking drills up to one quarter inch and the larger taking up to one half inch, the latter weighing six pounds. The respective speed for the three tools are 2200, 1400 and 1000 r.p.m. All these drills are fitted with Jacob Chucks. A screw driver attachment which is recommended for use on the medium size, can be furnished if desired. These tools can, of course, be employed for reaming and wood-boring, as well as drilling. They are manufactured by the Independent Pneumatic Tool Company, 600 West Jackson Blvd., Chicago.

SHORT STROKE CRANK PLANER

A specially designed Crank Planer with two heads on the cross rail has recently been placed on the market. The machine has a capacity of 32 in. in width and 32 in. in height, with a maximum stroke of 43 in. The uprights are of box section while the base is a one piece, grey iron casting. The hard steel gears in the driving box are of the sliding type and fully enclosed to run in oil. The driving gear, which is of the helical type, is 37 in. in diameter, 4½ in. face. All driving bearings are bronze bushed. An indicator is provided to indicate the length of the stroke, which can be set from the operating side. The operating speed ranges from 6 to 35½ strokes per minute. The cable has an adjustment of 20 in. along the bed and is of the double I-beam construction. The cable motion is controlled by means of a clutch and a brake operated by a lever at the operating point. This lever can be locked out of position so that the operator cannot possibly injure himself. The motion is of the double cycle type operating on the return stroke of the cable. This is transmitted to the cross rails through a rack and pinion. The planer is particularly well adapted for work on forming dies, locomotive cross heads, screws, wedges and all other short stroke work. These machines are manufactured by the Newton Machine Tool Works, Philadelphia, Pa.

FLEXIBLE POWER PRESS

An interesting design of Flexible Power Press has recently been developed and placed on the market. The pressure can be regulated at the will of the operator, this pressure ranging from a few pounds up to 8 ton. This feature makes the press especially adapted for straightening, pressing in bushings, or for assembling parts at each press. This has a scope of nine inches, which makes it very suitable for bush broachings and similar jobs. The upper head is supported on three steel columns, the table at the base being 30 inches from the floor. The posts are so arranged that the two front ones are in tension while the third post is under compression. The ram is threaded with a long Acme thread and run through a nut four inches in length. When operating, the nut turns with the ram until pressure is applied on the foot pedal. This pressure closes the asbestos-lined brake band on the nut and the ram passes down immediately through the latter until the pressure on the foot pedal is released or until the pressure supplied by the ram on the work equals the pressure supplied on the foot pedal. The ram is returned to its normal position by means of a spring around the top of the ram. The speed the ram travels is regulated by the speed of the driving pulley. The thrust is taken on a ball bearing between the nut and the main casting. These machines are manufactured by the General Manufacturing Company, 255 Meldrum Ave., Detroit, Mich.

B. & S. THICKNESS GAUGE

(Continued from Page 48)

car: for setting valve tappets, distributor headpoints, spark plug gaps, fitting pistons and determining the size of shims for joints or parts where there is play or looseness. The manufacturers state there is a broad range of use for this gauge.

This new tool is described in detail, in a pamphlet issued by the manufacturers.

BUILDING HUGE INTAKE

Four hundred men are employed constructing the intake at the mouth of the Chippawa river on the Chippawa-Queenston Hydro construction. Tomlinson, Macaw & McDonald, contractors, expect to have the work done before winter sets in.

Alternating with the intake gates there will be six big concrete tubes in the intake wall. These will be entirely submerged 38 feet below the surface. When the ice comes the gates will be closed, the submerged tubes alone being open. Most of the ice will be deflected back to the current by the gerat wall of concrete which extends up the river beyond the intake openings, and the rest will be opposed by the closed gates and slide along until it is caught once more in the power of the river. At the same time the water will flow beneath the ice through the submerged intake tubes and on through the Chippawa until it is claimed by the canal proper at the Montrose intake.

This great activity is going on within a big area temporarily reclaimed from the Niagara River by the construction of a coffer-dam of interlocking steel piling. The water was pumped out and hundreds of men, aided by drills, dynamite, shovels and powerful trucks, are working below the level of the great river, slowly scooping out the bed.

THE HYDRAUTOMAT

To utilize a fall of water in order to raise water much higher than the height of the fall seems an impossibility. Nevertheless it has been achieved by a British inventor, and without the use of any power except that supplied by the falling water. The action is entirely automatic—as the name suggests—and there are no moving parts except the sluices. The apparatus consists of a series of tanks and tubes built into the form of a tower suggesting a kind of water ladder. The paradox is only apparent, as the volume of water raised above the level of the fall is less than that flowing over the weir, although the efficiency is surprisingly high. The apparatus is expected to have a wide field of usefulness in irrigation especially where there exists a head of water that cannot at present be utilised in any other way. Another advantage is that a fall of dirty water can be used to lift clean water or any other fluid from another source.

AN EASY STARTING OIL ENGINE

Right through the history of the oil engine the difficulty of starting, especially when the engine is cold, has occupied the attention of inventors. Hitherto the most popular way of getting over the difficulty has been to use a high grade oil of the petrol type for starting and, after the engine has got going, to change over to the crude oil which forms the cheapest fuel for such prime movers. This arrangement, however, is really only a make-shift, and engineers have felt that the problem would not be really solved until an engine was designed to start "from cold" on crude oil. This problem has now been solved by a British firm. The new engine, after receiving the usual first impulse from compressed air, starts right away with the heavy fuel oil of the quality generally used in running. In point of fact, any fuel which can be pumped is suitable for this engine, which has been satisfactorily running on tar oil and even on sewerage grease. This grease is in the form of a thick paste and has to be warmed before it can be pumped. The engine is of the horizontal four-cycle type, and is of exceedingly simple and robust construction. The single cylinder type is made in sizes ranging from 20 to 150 brake horse power, and the two cylinder type go as high as 300 brake horse power.

In order to commemorate its 50th anniversary the Institution of Electrical Engineers of Great Britain has founded a bronze medal, designated the Faraday Medal, to be awarded once a year for notable scientific or industrial achievement in electrical engineering or for conspicuous services rendered to the progress of electrical science. The medal is to be granted without restriction as regards nationality, country of residence, or membership of the Institution.

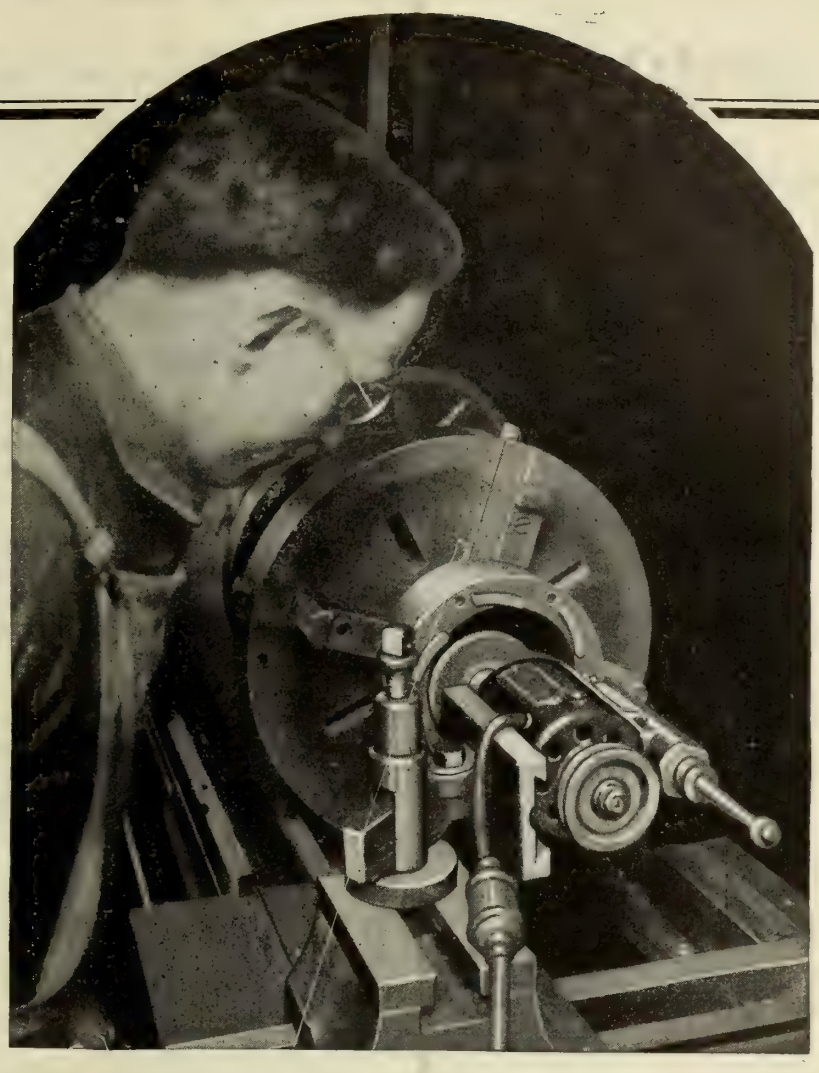
Although Great Britain is the home of the iron foundry it was not until this year that an exhibition devoted solely to foundry plant was organized in that country. The excellence of the display may, however, be regarded as atoning for the delay. Practically every type of furnace and appliance for melting and casting metal was exhibited. A British firm which specializes in large castings was unable, owing to the size of its usual productions, to find room for any of these in the exhibition. It therefore adopted the ingenious method of exhibiting models in wood about a quarter of the actual size of the steel casting. This firm is able to cast single pieces up to 110 tons; and during the war it supplied over one million tons of steel.

Are railway shopmen better paid than in private industry? is the question that arises in connection with the present labor trouble that is tying up a continent's supply of coal. In a statement issued by the National Industrial Conference Board, it is shown that, the average hourly earnings of the railroad employees stand at least 25 per cent. and weekly earnings at last 32 per cent. above those paid to men performing practically identical work in privately controlled plants. Railroad skilled shop mechanics include machinists, boiler makers, blacksmiths, sheet metal workers, and electrical workers, whose duties in the railroad shops are practically identical with the duties of men employed in commercial foundries and machine shops.

How to Get Greater Production at Lower Operating Costs.

EQUIPPING the tool room with one or more handy DUMORE high-speed GRINDERS means an increase of output and a lessening of costs on intricate grinding work. Because of their adaptability, these efficient grinders eliminate the need for costly tearing down of jobs and consequent wasteful delays.

Durably built in six useful styles and sizes, these compact high-speed grinders have long ago become indispensable in many varied industries. DUMORE grinders combine perfect running balance with correct cutting speed and work with a total lack of end play and absence of vibration—insuring speed and accuracy on the most delicate jobs.



The above picture shows a DUMORE grinder attached to the toolpost of an engine lathe at the Geometric Tool Company, New Haven, Conn. A cam for a die head has just been machined and the hole is being accurately ground without tearing down of the original "set up." Result—faster work at a decreased operating cost.

Let the DUMORE solve **your** grinding problems. Ask your dealer about them or write us for descriptive literature, and learn how DUMORE economy saves time and money. Write **to-day.**

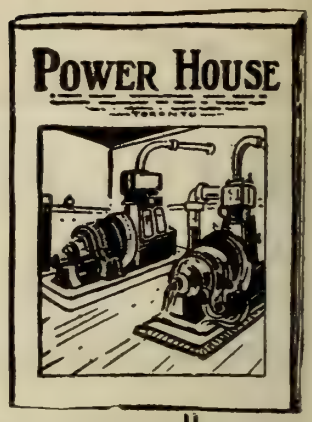
DUMORE HIGH SPEED GRINDERS



DO YOU Manufacture Industrial Equipment?

Are you a manufacturer of twist drills, hack saws, mechanics' tools, wire guards, bolts, rivets, paints—do you manufacture lines of any description that can be used in machine shops, metal-working plants, power plants or foundries? If you do the publications you see illustrated here (Canadian Machinery, Canadian Foundryman, and Power House) can build a bigger demand for your products.

This group of technical newspapers is read by the men who are prospective buyers of your lines. You can bring to the attention of these men the reason why they should demand your goods when purchasing from their dealers. You can effectively do this by placing a message in the paper which serves the field in which your products are sold.

CANADIAN MACHINERY AND MANUFACTURING NEWS is published weekly and covers the machinery, iron and steel and general metal-working industries of Canada.

POWER HOUSE is published semi-monthly; it serves steam, electrical, water and gas power plants, and the power houses of all general manufacturing plants.

CANADIAN FOUNDRYMAN AND METAL INDUSTRY NEWS is published monthly; it serves the grey iron, steel and non-ferrous foundries.

Each one of these publications reach proprietors, managers, purchasing agents, foremen—the men who direct the purchasing of goods. A message to these men in any of the MacLean Technical Newspapers is certain to have a strong influence.

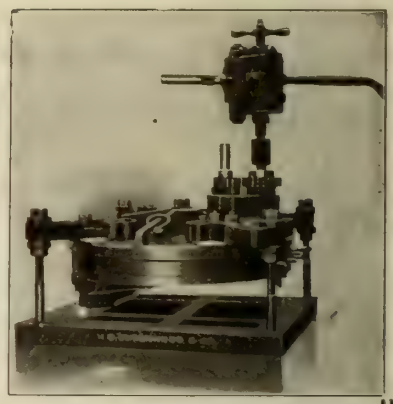
Roelofson Elevators

Once installed, the Roelofson Elevator—noiseless, smooth running, self-oiling, dust proof, and remarkably efficient—carries on its work with hardly any attention. In addition, its self-adjusting brake, phosphor bronze gears and worms cut from solid steel forging, make it absolutely safe and reliable. Enquiries solicited.

Roelofson Elevator Works

GALT, ONTARIO

Use This Planer for Deeply Worn Valve Seats



THE UNDERWOOD (Heavy Type) PORTABLE VALVE SEAT PLANER was designed to meet the demand for a machine that would face off deeply worn seats at one cut. That its work has been satisfactory is evidenced by the numerous repeat orders received from the most prominent shops.

It is rigidly constructed to stand heavy work without spring or strain. It will easily plane as heavy a cut as is required in valve seat work. The gears are cut steel. Two changes of speed are easily obtained by shifting the motor to either shaft. The tool post is strong and carries an inch square tool.

All exposed gears are guarded.

INTERNATIONAL
FOUNDRY TRADES EXHIBITION
BIRMINGHAM
June 15th—24th, (inclusive)

Engineering Production

The British Journal of Works Practice and Administration Circulating throughout the World will publish in the issues of

JUNE 8th, 15th & 22nd,

an authoritative description of the leading exhibits at the above Exhibition.

The equipment of the foundry with modern plant and appliances is becoming more and more recognized by engineers as a matter of great importance in economical production.

Those situated in various parts of the world who are interested in, but unable to visit the Exhibition, will find these issues of great value in giving information regarding the latest developments in foundry practice.

These issues will contain further instalments of the series on
WELDING AND CUTTING
and also many articles of an interesting production character, as well as the regular features such as the review of inventions, foreign trade notes and metal markets, etc.

EVERY THURSDAY 6d.

Subscription Rates: United Kingdom, 32/6 (Canada 32/6) Other countries abroad, 36/10, per annum, post free.

Publishers: ILIFFE & SONS LTD., Dorset House, Tudor Street, LONDON, E. C. 4.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

Foundation Ring for 20,000 h.p. I. P. Morris Turbine on 35 ft. Boring Mill

UNUSUAL SERVICE FOR UNUSUAL NEEDS

Machine builders can procure from us castings up to 75 tons per piece, in Grey Iron or Semi-Steel, rough or machined. We can arrange to give you special mixtures, true to formula and uniform throughout. Our machining facilities will handle anything turned out by the moulding department and comprise a number of large special tools, including the 35 ft. boring, turning and facing mill shown in the cut.

If you need castings of weights beyond ordinary foundry capacity, not easy to mould or of some special mixture, send us your specification and blueprints or sketches. You will receive our figures promptly and without obligation on your part.

Hydraulic Department

I. P. Morris Hydraulic Turbines and Centrifugal Pumps. The Larner-Johnson Hydraulic Valve in sizes up to 20 ft. diameter. Large Gate and Pivot Valves.

Paper Machinery Department

Fourdrinier Machines for Fine Papers, High-speed Machines for Newsprint or Kraft, Cylinder and Wet Machines, Millspaugh Suction Rolls, etc.

The Kaelin Electric Steam Generator

This Generator converts surplus alternating current into heat with a loss of less than 5 per cent. The coal saving usually pays for it in a short time. May we send you information?

Gives Up Boring for Grinding

Found the latter gave a better product at lower cost

If you are in doubt as to the superior finish imparted to cylindrical bores by the grinding process, we suggest that you communicate with the Superintendent of the Brunswick Refrigerating Company, New Brunswick, N. J.

This company produces refrigerating machines from one to twenty tons rating. The cylinders for these machines are made of unusually tough semi-steel. The bores are extra long, and when finished by boring—the former practice—were an expensive proposition.

Something less than a year ago a cylinder grinder was purchased for a try-out on this work and now it handles all of the cylinders used in the plant and has run night and day continuously for over six months. A better product at lower cost has resulted from HEALD use, and far less machine supervision is required.

HEALD

Cylinder Grinder

All Heald users have the same to say concerning Heald performance—"An excellent machine for our class of work."

Haven't you a boring problem that can be solved by grinding? Let our Service Engineer offer suggestions.

THE HEALD MACHINE COMPANY

35 New Bond Street, Worcester, Mass.

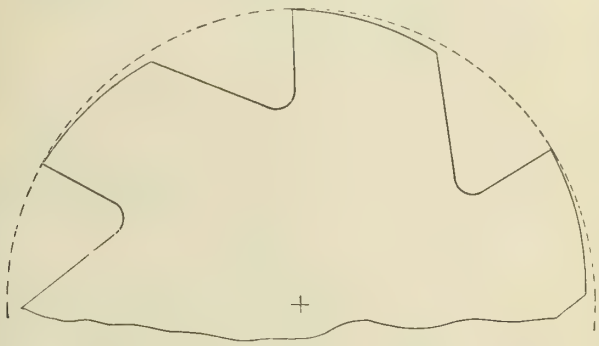
PRATT & WHITNEY

Reamers

With Eccentric Relief

THE cut below shows our patent eccentric relief which is an exclusive Pratt & Whitney feature. Eccentrically relieved Reamers, as made by us, have the distinguishing advantage that they can be sharpened by grinding on the face of each flute, thus retaining a true working size for a much longer period than is otherwise possible.

Pratt & Whitney Reamers are the only reamers having this eccentric relief, which should not be confused with the so-called "Eccentric tooth," which is nothing more than unequal spacing and adds nothing to the life of the tool.



Be Sure They Are Stamped Pratt & Whitney

--a stronger tooth--a smoother hole --no chatter--maintained size

All P & W Adjustable Reamers have **eccentric** relief, can be set to size without regrinding and can be made to **face the bottom of a hole.**

In order to set these reamers, it is only necessary to loosen the shoes and run back the nuts. The blades can then be pushed back and the shoes tightened slightly. Then, upon coming up with the adjusting nut, the diameter will gradually decrease until the desired size is obtained. Lock-nut and shoes are now firmly tightened and the reamer is ready for use. Quick, positive and convenient.

These reamers are made with 12 different sizes of bodies, giving an adjustment from .020 to .060 in., according to the diameter. Shell, hand or chucking reamers with the same number of body have interchangeable nuts, shoes, screws and wrenches. Shell and chucking reamers with the same number of body have interchangeable blades also.

"CANADIAN"
HAND POWER PUNCHES AND SHEARS

All Canadian hand power punches and Shears are made with "Armor Plate" frames.

This frame construction consists of a rolled steel plate having a tensile strength 7½ times that of cast iron. This strength permits of a machine much lighter and more compact than is possible with either cast iron or cast steel.

Let us know your punching and shearing requirements. We have an "Armor Plate" machine for the service. Remember our Armor Plate line comprises power operated machines as well as hand power.

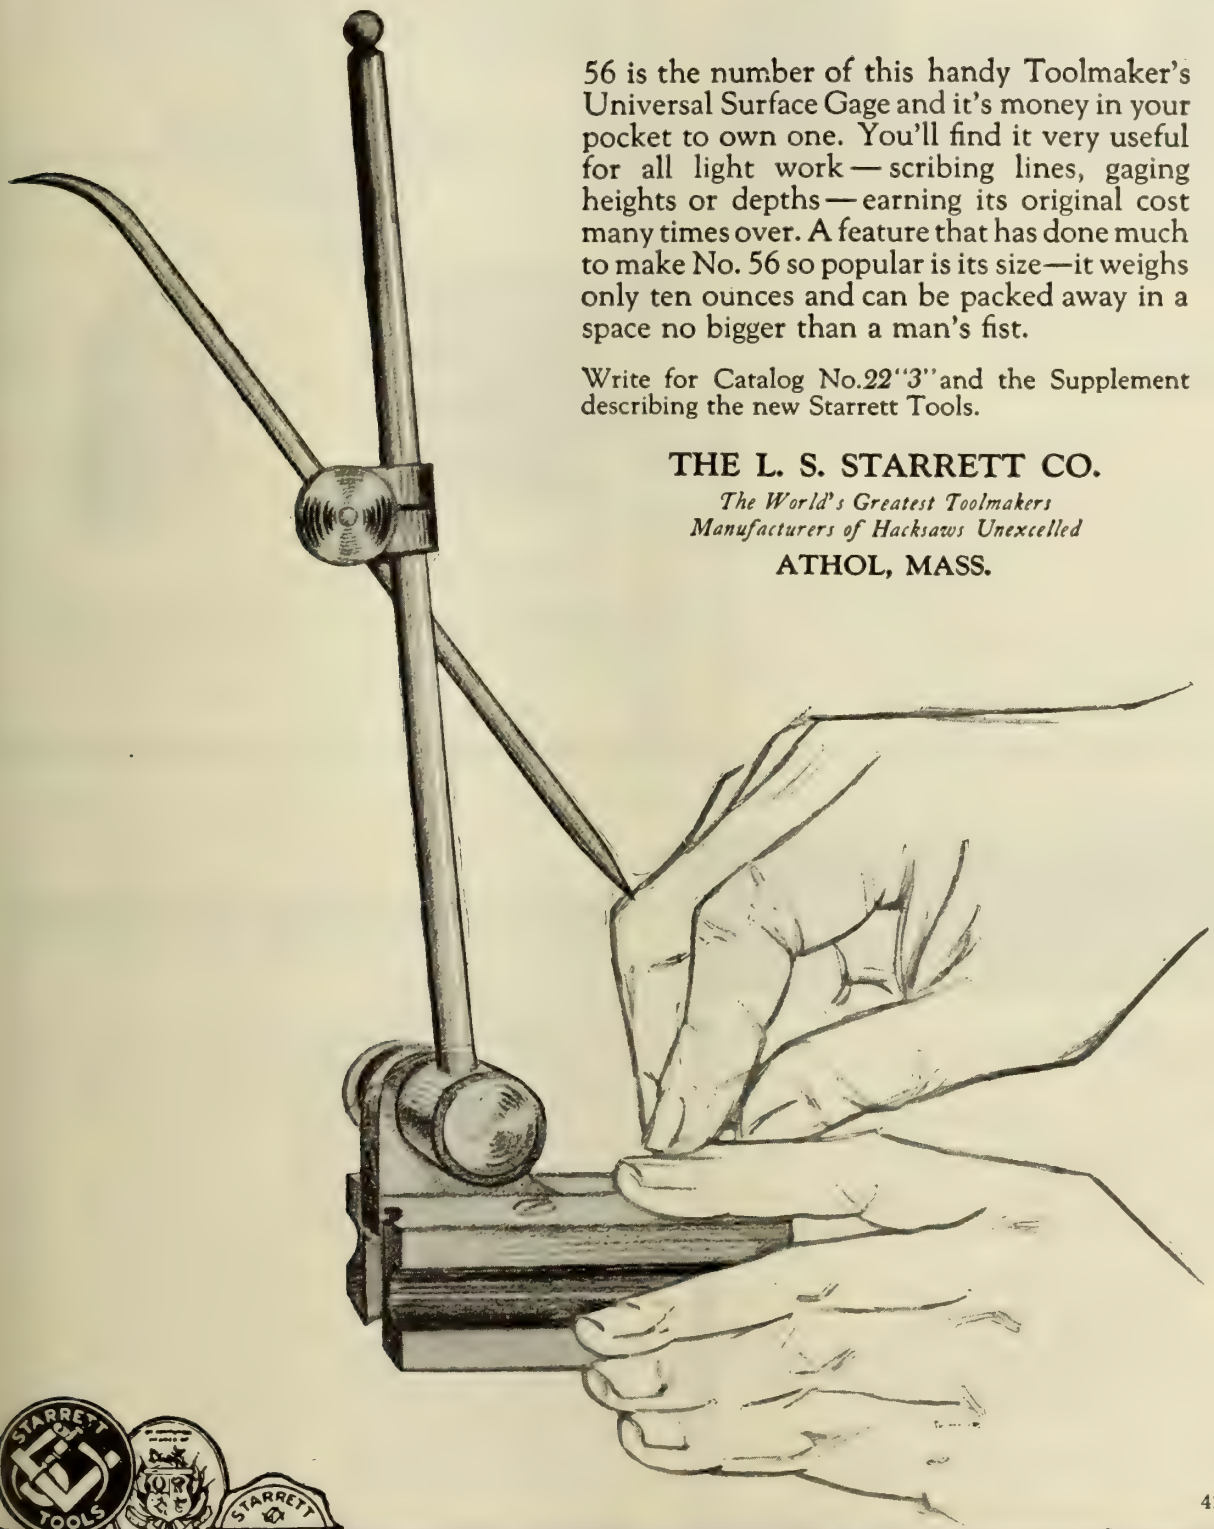
Money in Your Pocket



56 is the number of this handy Toolmaker's Universal Surface Gage and it's money in your pocket to own one. You'll find it very useful for all light work — scribing lines, gaging heights or depths — earning its original cost many times over. A feature that has done much to make No. 56 so popular is its size—it weighs only ten ounces and can be packed away in a space no bigger than a man's fist.

HOW MUCH ARE YOU WORTH?

In this country we reckon individual wealth in terms of a man's total assets. Jones is worth $5,000; Smith is worth $50,000; Brown is worth a million.

In France people estimate their wealth not by reckoning principal but by income—assured income. LeBlanc is worth 1,500 francs income a year; Garneau is worth 20,000 francs a year and Daudet is worth 250,000 francs a year.

The French can indeed teach us something. A man is worth only his absolutely safe yearly income, not the value of his securities, business and other assets that fluctuate in value.

Investments should not be reckoned in terms of their par value or even their market value but according to the income they bring. Investments have lost their value as such when they are not paying dividends or when interest is in default. The investments that will bring in the steady income are the ones you naturally seek. But how difficult it is to choose from among the array of tempting securities offered. So often securities that seemed so promising have proven utterly worthless.

THE FINANCIAL POST analyzes securities for investors. Whether you invest $500 a year, $5,000 a year or $50,000, you need its helpful weekly discussions on investment, business and finance. And you can profitably use its Service for Investors which gives individual advice on your own problems. You, as a subscriber, can ask as many questions as you like concerning your securities. They will be answered thoroughly and promptly.

Build for an assured income. By filling in the coupon subscribe today for the journal that will tell you what you want to know about investing—about your own securities.

DO YOU Manufacture Industrial Equipment?

Are you a manufacturer of twist drills, hack saws, mechanics' tools, wire guards, bolts, rivets, paints—do you manufacture lines of any description that can be used in machine shops, metal-working plants, power plants or foundries? If you do the publications you see illustrated here (Canadian Machinery, Canadian Foundryman, and Power House) can build a bigger demand for your products.

This group of technical newspapers is read by the men who are prospective buyers of your lines. You can bring to the attention of these men the reason why they should demand your goods when purchasing from their dealers. You can effectively do this by placing a message in the paper which serves the field in which your products are sold.

CANADIAN MACHINERY AND MANUFACTURING NEWS is published weekly and covers the machinery, iron and steel and general metal-working industries of Canada.

POWER HOUSE is published semi-monthly; it serves steam, electrical, water and gas power plants, and the power houses of all general manufacturing plants.

CANADIAN FOUNDRYMAN AND METAL INDUSTRY NEWS is published monthly; it serves the grey iron, steel and non-ferrous foundries.

Each one of these publications reach proprietors, managers, purchasing agents, foremen—the men who direct the purchasing of goods. A message to these men in any of the MacLean Technical Newspapers is certain to have a strong influence.

Write for complete Data.

HEPBURN

Power Presses

For Long Service—

After all, you could no doubt buy any number of presses that would give the same production the first few weeks of operation.

But after a year—two years—three years—What then? If it is a **Hepburn** built Press you get production unslackened by constructional weaknesses.

Hepburn Power Presses are strong and well built. The cranks are made from solid forgings and give long strokes. Quick adjustability a feature of every press. Write for specifications. We also make Vertical Engines, Compressors, Winches, Planers, Steam Pumps, Cranes, Special Machinery Forgings and Castings.

YOUR CHAIN OF CONFIDENCE—AND

BROWN & SHARPE MACHINISTS' TOOLS

The manufacturer in equipping his plant with Brown & Sharpe Machinists' Tools links together an unbreakable chain of confidence—a chain that starts with his receiving clerks, and never ends.

First Link

Brown & Sharpe Machinists' Tools accurately test the size of incoming material to see that it meets specifications. The first link in the chain of confidence is established—your certainty that your stock is of specified sizes.

Second Link

Brown & Sharpe tools and gauges check up the accuracy of your machine production. The faith of your operators in these fine tools helps them to work with sureness and speed. Another link is joined to the chain—your confidence in the quality of your production.

Third Link

At the final inspection, Brown & Sharpe Tools place the seal of your approval on your products. If your products conform to the tests of these fine measuring instruments—your products must be right.

You are willing now to let the customer be the judge. Here is the third link in the chain—your confidence in the accuracy of your products.

Added Links

Tell your customers that your factory is equipped with Brown & Sharpe Tools. Then every new customer adds a link to an unending chain of good will and confidence in you and your products.

People have faith in the dependability and quality of products made with the help of Brown & Sharpe Machinists' Tools.

It rests with you to determine how long and how strong your chain of confidence will be.

Send for Catalog No. 28
which describes 2,000 tools.

Saving Time And Money With Portable Tools

Rapid Development of This Type of Equipment — Taking The Machines to The Work—Making Repairs With Portable Welding Outfits—Handling Loose Material Economically

FEW labor-saving devices have shown more rapid development than the widening range of portable tools that are now extensively used in every phase of industrial life. It would be difficult to classify exactly what portable equipment really is, but the general meaning would be a tool or machine that can be conveniently transported from one location to another for the accomplishment of mechanical operations. The range of portable tools is almost unlimited, as the list is comprised of all manner of small hand tools, up to and including many of the heavier machine tools used in large engineering plants, where it is often more desirable to bring the tools to the work than to carry the work to the machines. In the latter instance the floors are generally fitted with large surface plates so that machines are properly aligned when located near the work by means of the overhead crane. Among these machines might be mentioned large radial drills, slotting machines, large boring tools, millers, etc. From this it may be seen that it is almost impossible to properly define a portable tool.

Air and Electric Tools

Probably the tools that are the most deserving of the name portable, are the varied types of pneumatic and electric appliances that have been developed for the speeding up of work formerly performed by hand labor. The conservation of man-power has been greatly enhanced by such equipment and the great saving effected has been reflected in the steadily growing demand for all classes of light portable air and electrically operated hand tools.

The most suitable tool for any particular purpose would naturally be suggested by the nature of the specific operations and the local conditions governing the source of power. Where it is a question of percussion, such as chipping, riveting, sand ramming, etc., the choice would obviously be the pneumatic tool, as the reciprocating motion of the air plunger is best adapted for such operations. Where it is a matter of drilling, reaming, grinding, and other work, where a rotary motion of the tool is required, the selection would depend on the nature of available power, as both air and electricity are extensively used for work of this character. Generally speaking electrically-driven portable tools are best suited for grinding operations, owing to the greater speed that may be obtained with this apparatus.

In the assembling of heavy machinery and in general repair work, the small portable tool is indispensable. The hand-operated ratchet drill is still to be found in many shops, but its application is confined to a much smaller range now owing to the greater production qualities of pneumatic and electric tools for this purpose.

Foundry Equipment

Before the event of the pneumatic hammer the work of fettling castings in the foundry was a tedious and expensive operation, frequently requiring two men for the work, one holding the chisel while the other used the hammer. This work is now accomplished almost entirely by means of air tools, and one man performs the work formerly requiring from one to six. Sand ramming in the foundry is another operation that is now advantageously handled by means of air-operated tools. Before the advent of the sand rammer the preparing of large molds was a laborious job, but with these modern air tools

Grinding a large die block.

the work can be performed with less effort and with greater satisfaction, and likewise considerable saving over the old method. The portable grinding outfit is another serviceable tool that has met with considerable favor in foundry practice. A much higher finish can be given to a rough casting by grinding the portions that have been previously chipped or snagged with the air hammer.

A workman's capacity to produce results is determined by his reserve energy. His ability will decline as this energy is expended. The development of mechanical appliances has enabled the workman to produce considerably more work than was ever possible under the old hand method. The physical effort required of a man when using light mechanically-operated hand tools, is much less than that necessary under the old system, and more and better work is the result.

Large Portable Tools

While the large machine tools are not generally included in the portable class, there are many instances especially in the larger engineering plants, where it is often advisable and perhaps necessary to take the tool to the work owing to the inconvenience and great expense that would be entailed in the frequent movement of massive castings from one machine to another. Under such circumstances it is within reason to classify these tools as portable. In the case of bulky castings for large engine work, turbo-generators, and heavy machinery, the necessary equipment for performing many of the machining details is taken to the work and located, by means of the overhead crane, in the desired position for doing the work. In this way it is often possible to perform numerous operations of a varied character on a large casting without removing it from its original position. In order to carry out this class of work successfully it is imperative that the shop floor be fitted with level plates on which the various machines can be located, so as to minimize the need of aligning the tools before machining operations are commenced.

Welding Outfits

Included in portable equipment now in constant service in industrial plants is oxy-acetylene and electric welding. Where breakdowns to machinery occur at a distance from a repair base, and where the removal of the broken part would entail prohibitive delay to regular operations the presence of a welding outfit has often saved the situation. The cost of such emergency repairs has often meant the saving of thousands of dollars that would otherwise have been expended in replacements, in addition to the loss of production resulting from the unavoidable shut down.

Elevating Appliances

The handling of material such as loose earth, coal, ore, etc., is often economically performed with portable conveyors and elevating apparatus. The loading and unloading of such materials by means of the ordinary hand shovel required the services of a large number of men, whose ability rapidly depreciated as the day progressed. The mechanical loading conveyor conserves the energy of the workman and reduces the number of men required to the lowest possible minimum, as a machine of this description can be operated continuously by one man and moved from place to place with the greatest ease.

From Office Boys to $30,000 a Year

Slow Steady Progress to Responsible Positions—Man With the Right Stuff Goes to the Top—Recreation and Clean Living Essential to Success—Salesman Must Have Personality.

AN ANNOUNCEMENT was recently made by the Standard Oil Co., of Indiana, that three men of its rank and file—two of whom started as office boys and the third as a dray-driver—have been made directors of the company at a salary of $30,000 a year each.

No sudden rise was theirs, but a slow steady advance. According to their own estimates they were endowed with no exceptional talents. They consider themselves average men, possessed of average abilities and presented with average opportunities. Their genius consisted in making the most of these opportunities. The story of their careers, as related by themselves to the "New York Sunday Times" should prove an inspiration to all young men who possess the capacity for hard work. The three men are Robert H. McElroy, traffic manager; Edward J. Bullock, director of purchases, and Thomas J. Thompson, general manager of the sales department.

"I was fortunate enough," said Mr. McElroy, "to secure association with a business organization which represents true democracy—an organization wherein every employee, no matter what his financial or social status, is given opportunity to rise to the most important executive position within the company's power to bestow.

"In the Standard Oil Company there is no such thing as 'pull.' Every man stands on his own feet, and if he has the right stuff in him he will inevitably go to the top. I, who began life as a messenger boy, am no exception among the executives of the Standard Oil Company of Indiana. Every member of the board of directors and every executive of any importance in this company is a man who has had to fight his way up. Many of them have acquired their education through correspondence and night schools. There are, of course, many college men among our executives—men who hold masters' and doctors' degrees, but they, too, had to start at the bottom of the ladder and work their way up, proving they had a lot more in them than just education.

"Next to opportunity," Mr. McElroy continued, "the most important factor in success is the incentive to fit oneself to take advantage of the main chance. My incentive has been a wife and children.

"Leaving school at twelve, I ran a corner news stand for a while. One of my customers was a wealthy man and one day I asked him if he couldn't get me a 'decent' job. He did—as messenger boy at $15 month for the Chicago, Milwaukee & St. Paul Railroad. In the past year we have had messenger and office boys refuse to accept a job with us at $60 a month. But I thought it was a pretty decent job at $15 a month, and so it proved to be.

The man who got it for me is eighty years old to-day and when I was made a member of our Board of Directors a few weeks ago, I received a nice letter of congratulation from him.

"Two months after I got the job, I was promoted to office boy. In the meantime I had enrolled in the Chicago North Division High School at night. I worked from 6.30 a.m. to 6.30 p.m. six days a week and every other Sunday, and studied and attended classes at night. I thought it was pretty tough then, but now I know it was good for me.

"My night school work helped me and soon I was promoted to clerk, and then went up through various positions until I was made chief clerk. In 1906 I was offered a position in the traffic department of the Standard Oil Company of Indiana. I made inquiries, found it was an organization where every man had a chance, and took the job. In 1917 I was made traffic manager of the Marketing Committee.

Loyalty a Big Thing

"Any boy," added Mr. McElroy, "who has the right stuff in him, who is willing to work at his job and study after working hours, who will keep his eyes open till he can place himself with a thoroughly democratic organization headed by men of integrity who give a square deal to employees, can achieve the same success that I and many of my associates have.

"He must, however, always extend absolute loyalty to his employer, and just as great a loyalty to his subordinates. The man who fails to be loyal to the men under him, who refuses them a square deal, or tries to shift on them responsibility for his own mistakes, won't get very far. Be loyal to your subordinates and they will be loyal to you, and once a man gets a loyal organization back of him. he needn't be afraid of anything.

"Decent living and decent morals are also essential. I don't mean that a man shouldn't play. He needs recreation. But he must not make play his chief aim. When one gets to be forty-five, his early efficiency in baseball, tennis, golf, pool, etc., won't have gotten him very far. Play enough to keep healthy in mind and body, but don't let play interfere with your job."

Thirty seven years ago Thomas Thompson entered the employ of the Standard Oil Company of Indiana as a drayman. The next year he was promoted to be driver of a tank wagon. He realized that this was as far as he could ever get with the educational equipment he then possessed. Like Mr. McElroy, he started to study. He mastered not only the subjects necessary to gain him promotion to some position near the wheels of the great corporation, but many academic subjects as well. His promotions were slow, but steady, and on Dec. 10, 1920, he was appointed general manager of the sales department. After that his appointment as a Director of the company followed as a natural sequence.

"I have but one fundamental formula for success," said Mr. Thompson, "and that is work, work, work. I do not care what a man's abilities are—he may be a genius of the first water—he will never attain success without careful preparation and extended effort. The world is filled with failures who possessed all the talent necessary for success, but lacked the willingness to work for it. On the other hand, there are thousands of successful men who possess mere ability rather than genius who have won their places simply by hard work and square dealing.

"One of the policies adopted by our company is that the selling organization must work just as hard for the customer as for the company. When I began selling, I did not try to sell myself, but concentrated on trying to sell the Standard Oil Company of Indiana to every customer I approached.

"Many salesmen fail when they strive to sell themselves rather than the company they represent. When a man obtains orders merely on his personality and neglects to sell his company he stands alone in an exposed position, ready to be bowled over by a competitor's attack. No matter who the salesman is, there is some other salesman who possesses a more pleasing personality, and the competitor is going to send that man into the field, with the result that the salesman who depends on his personality rather than on the quality and service given by his company is out of luck. The other fellow will get the business. But had the salesman sold the company, the quality of the goods and service rendered, he would have convinced the customer that no other company could give such service or better quality at a better price, and it would have meant the holding of the business. The salesman who sells his company rather than himself does not stand alone; he has an organization back of him.

A "Different" Salesman

"One must be as loyal to a customer as to himself. Lots of times I have had orders come in which I knew were

(Continued on page 21)

Practical Method of Testing Centrifugal Pumps

Individual Tests Given to Each Unit—Proved Efficiency When Placed in Service—Interesting Method of Mounting Motor—Speeds Recorded on Vibration Tachometer.

DEFINITE characteristics of centrifugal pumps cannot be as accurately calculated in advance, as those of reciprocating pumps of various designs, and for that reason manufacturers usually prefer to test the former types before placing them in service. The reputation of the pump is thus guarded and at the same time statements, and guarantees as to performance, can be intelligently and confidently made.

Messrs. Darling Bros. of Montreal, manufacture a wide range of sizes of centrifugal pumps. Every pump is subjected to an individual test. To standardize results, and to make tests thoroughly and economically, a very interesting apparatus has been developed. Most of the impellers are bronze castings and practically all the pump casings are cast in iron.

It is not practical to machine some of the surfaces exposed to the liquids to be pumped, and in spite of the fact that the greatest care is taken in preparing the cores and setting them in the mold, small variations are found. This is only natural as molding can not be done to within a few thousandths of an inch. These variations are only infinitesimal but are reflected in the fact that capacities of the pumps vary slightly. For that reason this firm decided to test every centrifugal pump they built, and to do so in a very thorough manner under varying conditions. This would enable them to state with confidence just what every unit would do when placed in service.

Testing Appliance

The present apparatus was not designed, but rather developed from a basic idea. Improvements have been made from time to time, and now the apparatus is very complete. It is the intention of the firm to design a very complete apparatus from the data obtained in developing the original unit, which we are about to describe. The base consists of the bed of lathe. On one end of the base, or frame, is mounted a d.c. Allis-Chalmers-Bullock electric motor, which is used to drive the pumps to be tested. As the current supplied the factory is a.c. it was necessary to procure a source of supply of direct current. Nearby is located a belt driven d.c. Canadian General Electric generator of 6 k.w. capacity. The field rheostat of the generator, as well as motor rheostat, are located on the frame of the testing apparatus carrying out the idea of centralized control. At one end of the apparatus a switch board is located. This board carries the starter of the motor, an ammeter and a voltmeter.

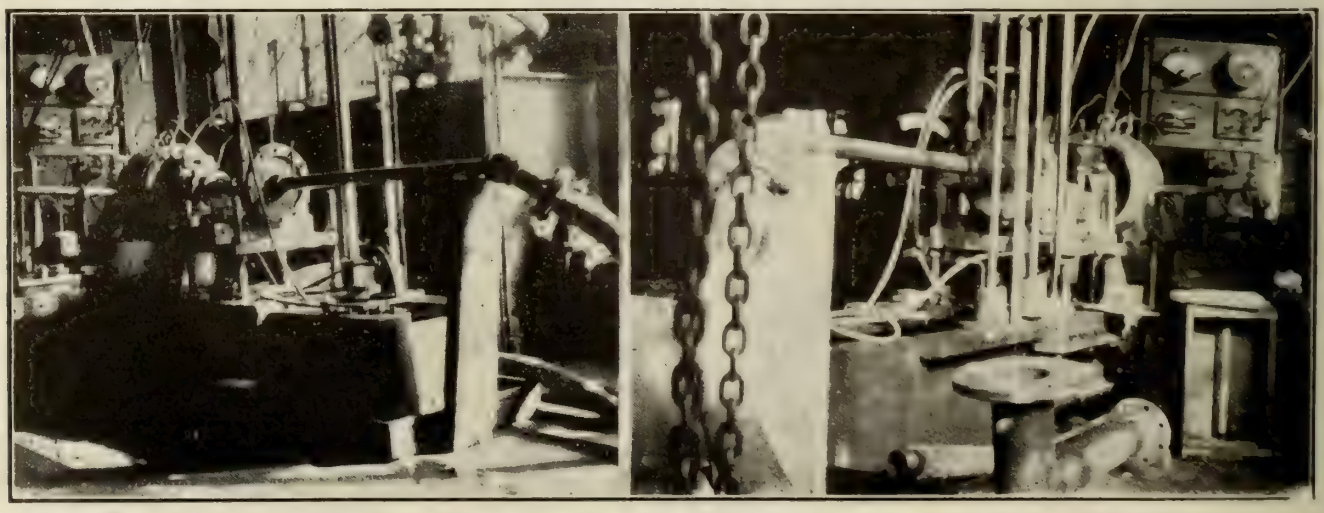
Unique Motor Mounting

The motor is mounted on the testing frame in a unique manner. It is held suspended at a fixed height in two bearing standards. The motor frame is free to rotate (on ball bearings,) about the centre line of the armature shaft. The armature is free to rotate with its shaft, independently of the motor frame, as in ordinary installations. The feet of the motor frame are in mid-air some eight or ten inches above the ways of the testing apparatus. A piece of 1 1-2 inch pipe is threaded into the side of the motor frame so that when the feet of the motor frame are in the horizontal plane, the pipe extends horizontally, at right angles to the centre line of the armature shaft, and with the axes of both pipe and shaft in the same horizontal plane. This arm is made to press on the platform of a very sensitive Toledo scales of the dial indicating type and originally designed for shell work. A special dial has been placed in the scales, reading pounds and tenths of a pound. An ingenious arrangement has been provided to take up the effect of any angularity of the arm. This is shown in Fig. 1. It might be mentioned that the effective length of the arm, measuring from the centre line of the shaft, is 31.416 inches, or ten times pi., which greatly facilitates calculations. The armature current is brought from the generator to two binding posts on the stationary standards which support the motor. The current is carried over to the frame of the motor, and thence to the brushes and field coils, (the motor being shunt wound,) by means of two conductors of brass wire cloth, which are very flexible and offer but infinitesimal resistance to the mechanical turning of the motor frame, which turning effort, or torque, is thus registered accurately on the scales.

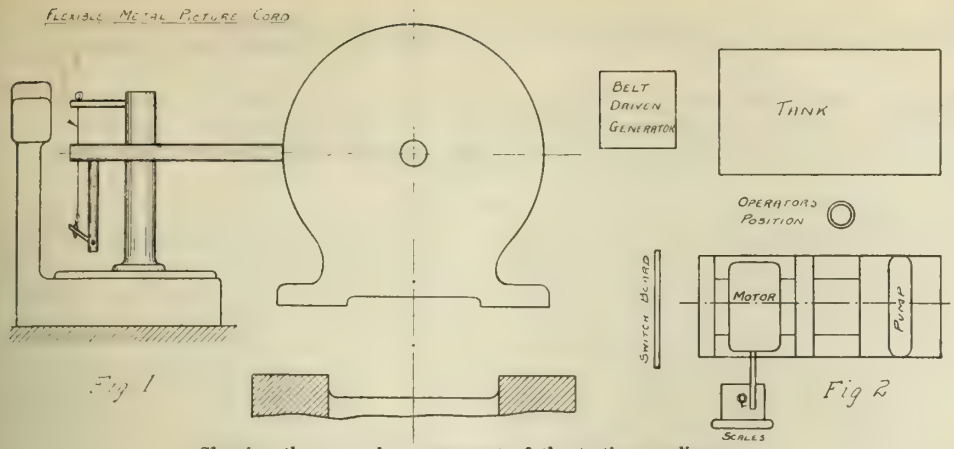
There are arrangements which provide for running the motor either way so that right and left hand pumps can be tested. Speeds up to two thousand r.p.m. are obtainable from the motor. The motor and pump speeds are recorded through the medium of a portable vibration tachometer.

Power Delivered

First impressions might suggest that the voltmeter and ammeter were used to determine the mechanical power delivered to the pump shaft. As electric motors operate at various efficiencies under varying load and speed conditions, this method would involve a new set of variables in the calculation and thus open up a new field for error. A characteristic curve of the motor would be necessary. To avoid these complications the ingenious and accurate dynamometer device is used to determine more directly the mechanical power delivered, without considering either mechanical or elec-



Two Views of Darling Bros.' Installation For Testing Centrifugal pumps.



Showing the general arrangement of the testing appliance.

trical efficiencies. The meters on the switch board are used largely to determine the loads on the motor and generator and thus guard against overloading. As before stated, the generator is a 6 k.v.a. machine, but when large pumps are being tested, a steam driven generator of larger capacity is used.

There is a flexible coupling on the motor shaft which is used to connect up to the shaft of the pump to be tested. The coupling also provides for the small amount of end play that it is desirable to have in the pump and in a motor of this type.

Locating the Pumps.

On the ways of the apparatus, toward the end remote from the motor, a sliding carriage is located. It presents a flat square surface and is gibbed to the ways. Provision for locking in any desired position is made. This longitudinal motion is used in locating the pump. Vertical adjustment is also provided. There are four threaded posts of generous cross section, located, one at each corner of the carriage. A platen is supported on these posts. Lock nuts above and below the platen permit of its adjustment to any desired vertical position. When a pump is being tested, the pump frame is bolted or clamped to the platen. The adjustments just described permit of the necessary movements required to line up the pump shaft with that of the motor.

Hydraulic System

The hydraulic arrangements are very complete. A 900 gallon steel tank supplies the water. It is open to the atmosphere. The suction pipe leads from the bottom of the tank. A complete arrangement of valves permits suction lines of desirable size to be coupled up. A combination of pipe and hose is used in nearly all lines for convenience in coupling up. A small hose is led off from the suction line to a mercury manometer, which indicates the amount of vacuum.

The discharge line is led to a 4 in. pipe header located near the ceiling. From the discharge line also a small line is taken, which line is led to a mercury manometer, which is graduated to read directly in feet of head and pressures, up to 70 feet and 30 pounds, respectively. For higher heads and pressures a specially graduated pressure gauge is connected to the line, there being a small "T" in the manometer line and valves which would permit the cutting out of the manometer.

From the header into which the discharge is led, there are three pipes leading vertically down to the tank. There are two 2-in. pipes and one 3-in. pipe, each provided with a Venturi tube. One 2-in. pipe has a 2-in. x 23/32 in. throat, the second 2-in. pipe has a 2-in. x 1-1/16 in throat, while the 3 in. pipe has a 3 in. x 1-3/4 in. throat. Each Venturi tube is connected with a third manometer. Three scales are provided. These scales are removable and to read the discharge from any of the tubes it is only necessary to place on the proper scale and to cut out the other tubes. This is easily done as valves are provided. The discharge can be made through any one of the three tubes, or any two, or all three can be used at once. To get the total discharge in the case where more than one tube is used it is necessary to read the discharge of each tube separately. The whole apparatus is so designed that an operator can remain at one point and control and gauge every part of the apparatus.

The device has been developed largely in the plant and at no small expense. The calculations are very simple and in most cases the data is read directly. The only calculation is that of the power supplied When this is figured, it is a comparatively easy matter to deduce all the data required. As variable velocities are possible, the action of pumps under a wide range of speeds can be obtained. Valves are placed in the lines so that the vacuum in the suction line can be varied, and also the discharge pressures by valves in the lines containing the Venturi tubes. Complete data of the performance of a pump can be obtained in a remarkably short space of time.

FROM OFFICE BOYS TO $30,000 A YEAR

(Continued from page 19)

greater than the customer's needs. I saw that the agent or the merchant was overstocking. I have made many a personal trip to see a customer and argue with him until he reduced the size of his order. I would rather sell a customer one barrel of oil a year for fifteen years, if that were his requirement, than to sell him fifteen barrels in one year and wait fifteen years until he had used that up.

"A good salesman will know his customer's needs and protect them, sometimes protecting his customer against himself. It may mean a smaller order, but the salesman who protects his customer against overstocking will win in the long run. Following the policy of our company, I have never yet permitted the size of an order to tempt me into accepting it if I knew it were contrary to the best interests of my customer to buy or use that much oil, even if the customer did not know it himself."

The Way to the Top

"E. J. Bullock climbs to success via a soap box, proving that this well known article may be put to more constructive uses than of serving as a rostrum for Bolshevist oratory," was the caption the Stanolind Record, a Standard Oil house organ, used in announcing Mr. Bullock's elevation.

"Back in August, 1889, R. G. Collins, at that time manager of the Milwaukee division," said the Stanolind, "hired the smallest office boy then at large. He wore knee-breeches and had a piping voice, and was the last youngster in the world to be suspected of ever aspiring to the height of six feet; yet he cherished that ambition and numerous others besides. To-day this diminutive youngster, is a husky specimen, six feet tall.

"Bullock's first step upward came soon after his employment. Essaying to answer the telephone, he was chagrined to find that he could not reach it, but Mr. Collins, noting the difficulty, provided him with a soap box.

"Fifteen years later, in 1905, he came to Chicago as assistant manager in the lubricating oil sales department. In 1905 he was made manager of the Chicago sales division, and when the oil products purchasing department was created in 1919 he was placed at its head. In 1921 he became director of purchases, having supervision over the entire purchasing department, and still giving his personal attention to the buying of oil products. On his shoulders rests the responsibility of keeping the refineries supplied with crude, which he must procure at prices which will permit operation at a profit.

"Mr. Bullock's theory is that if a man devotes his time, attention, intelligence and energy to the interest of the company which gives him employment, he will gain recognition and a sure reward."

A SMALL POWER PRESS

In the manufacture of many articles, small stampings or pieces of pressed metal are used in enormous quantities. Frequently, it is the custom for manufacturers who require such stampings to purchase them from firms specially equipped for their production. In other cases, however, where they are merely accessory to some machine or appliance, it is very convenient to be able to make them on the spot as required. For this purpose a British firm has produced a small power press of a very simple type and at a low cost.

Progress of Standardization Work in Canada

Many Industrial Firms Interested—Sectional Committees Formed—Developing a Uniform Product—Benefits of Far-Reaching Character—Domestic Industry Receives First Consideration

By R. J. DURLEY, M.I.C.E., M.E.I.C., Am. Soc. M.E.

STANDARDIZATION work undertaken by the working committees of the C. E. S. A. commenced, in every case, at the request of responsible parties interested. The progress to date has dealt almost exclusively with the preparation of specifications for material or manufactured products rather than with dimensional work.

The main committee has felt that such questions as may arise regarding dimensional standardization in Canada would most frequently deal with the advisability of adopting, possibly in a slightly modified form, standards already agreed upon by bodies undertaking this work in the United States, Great Britain, or elsewhere. In other words, it has not seemed likely that many instances will occur where the work on dimensional standardization can be completely independent of the work done in other countries.

Sectional Committee Work

One of the first C.E.S.A. sectional committees to be formed was that on machine parts under the chairmanship of A. R. Goldie, of Goldie & McCulloch, and under this sectional committee there will naturally be organized, from time to time, whatever working committees are needed. There is of course no intention to undertake any action tending to limit the freedom of the designer by insisting on uniformity of design of complete machines. Parts and components used in quantity by all manufacturers of a given line are naturally the object of the association.

The questions so far considered by the sectional committee just named have been matters in which co-operation has been requested by the A.E.S.C. One case of this kind is now before the committee, namely: the proposed American standards for the dimensions of shafting keys. In such a case the American proposals are usually forwarded to us before they are finally adopted in the United States, and we are thus given an opportunity of considering and criticising them and advising how far the proposed dimensions meet the views of Canadian manufacturers.

Quite recently, H. G. Bertram of John Bertram & Sons Co., Dundas, who is a member of Mr. Goldie's committee, has suggested that much useful work might be done by the C.E.S.A. in developing standards for machine tool parts, which have not yet been dealt with in the United States except by firms individually, who have standardized the dimensions of such items as crank handles, machine handles, keys, splines, nuts of various types, taper and cotter pins, oil rings, cap screws, washers and wrenches, for use in their own establishments. Mr. Bertram gives as an example of this, work which has been done by his own firm in conjunction with other firms attached to the Niles-Bement-Pond organization. He believes that if standards of this kind, which have been adopted by individual firms in Canada, were given publicity, so that other manufacturers could compare them with their own, the way would be paved for agreement on dimensions of these parts, covering all firms in Canada engaged, say, in the manufacture of machine tools, or in other branches of machine manufacture, as the case may be.

Economic Importance

It is hardly necessary to enlarge on the economic importance of dimensional work of this kind. Agreement throughout Canada, for example, upon the standard sizes for cap screws, would enable their manufacture in larger quantities, and presumably at a lower cost, so that the sale of a uniform product to a larger number of individual purchasers would be possible. This seems particularly important in a country like Canada where the number of firms engaged in any one industry is not large, and where individual divergencies in practice thus lead to a demand for small quantities of many unnecessary varieties of detail parts to be furnished by outside concerns.

While the influence of the mechanical industry in the United States upon ours must inevitably be very great, it does not seem necessary that we should in all cases wait until dimensional standardization work has been accomplished there. It is often easier for us to obtain agreement among manufacturers in a given industry than would be the case in the same industry in the United States, where the number of divergent views is likely to be so much greater.

Perhaps the most striking example of dimensional standardization can be found in the admirable work of the Society of Automotive Engineers as applied to the automobile industry, and while it is not likely that we shall be able to accomplish anything of so far-reaching a nature, say in the machine tool industry in Canada, there seems no reason why the benefits of dimensional standardization should not be available here to a much greater extent than has hitherto been the case.

Many Different Features

The experience of the last two years has shown that standardization work in Canada presents features not only of particular interest but also of special difficulty. While it would appear at first sight that in many instances British or American standards could be adopted without change, owing, in the former case, to the fact of geographical proximity and industrial connection, and in the latter, to the intimate commercial relationship existing, this is not always found to be the case in practice. Differences in industrial conditions and in the class of material and workmanship available, differences in climatic conditions, and in legislative restrictions, tend in many cases to make differences in practice necessary or advisable.

Committees have to bear in mind in framing their requirements that while domestic industry must receive the first consideration, the interests of the purchaser and importer are also affected, since in many branches it is necessary for us to import not only material in a raw or semi-finished condition, but also manufactured machinery or completed engineering products.

Co-Operation Advisable

Speaking generally, it may be said that as regards dimensional standards, as, for instance, in ball bearings, screw threads, gearing, and the like, American practice is usually followed, and in many cases it may be found desirable to adopt American standards without alteration. In other cases, as, for example, the preparation of specifications for material, the influence of local conditions is often strongly felt, and in such instances specifications of our own, possibly differing from both British and American practice, are being developed. The closest co-operation is, however, being aimed at, both with the British Engineering Standards Association and with the American Engineering Standards Committee, and it is even hoped that in the case of certain British and American Standards it may be possible for the Canadian organizations to assist in bringing about international agreement.

Work in Railroad Field

In connection with railway work, the interchange of traffic obviously makes it necessary for Canadian practice to agree substantially with American standards as regards locomotive, car and track work, and our railway bridge specification is in general agreement with a practice adopted by the American Railway Engineering Association. During the past eighteen months the Canadian Association has published among other subjects, specifications for steel railway bridges, for distribution, type transformers for galvanized telegraph and telephone wire,

Methods of Hardening High Speed Steels

No Scaling Takes Place in Salt Bath Practice—Crucibles Have Short Life—Rapid Heating in the Lead Bath—Oil or Gas Fired Semi-Muffled Furnaces Generally Adopted

SALT BATH hardening was first introduced in 1902. Ordinarily, barium chloride is the salt used and the operating temperature is from 2,000 to 2,100 deg. F. (1,093 to 1,149 deg. C.) Graphite crucibles are used for holding the salt, the life of these crucibles being from six to eight heats. The tools to be hardened are immersed in the hot liquid and the tools permitted to remain until the entire mass of the tool has attained the temperature of the bath. These tools are then usually oil-quenched, and drawn to from 400 to 600 deg. F. (204 to 316 deg. C.) in oil, depending upon the kind of tool.

No scaling takes place by this method thus producing a cleaner tool than in muffle furnace hardening, but the method has the following disadvantages: (1) The quenching temperature is too low. (2) Soft scale is sometimes produced. (3) Blistering and pitting sometimes occurs. (4) Pots are very short lived.

It is a well known fact that to obtain the highest degree of red-hardness, partial austenization must take place. This means quenching from a temperature of 2,200 deg. F. (1,204 deg. C.) and upward; indeed, the higher the quenching temperature above 2,200 deg. F. (1,204 deg. C.) up to about 2,350 deg. called "secondary hardening"—the added hardness gained by tempering quenched steel. We have heated small test-pieces of high-speed steel 1½ hours in a barium chloride bath at 2,100 deg. F. (1,149 deg. C.) but the microstructure was the same as when left in the bath just long enough for the heat to soak through.

Blistering and pitting of tools heated in a barium chloride bath are said to be due to particles of the graphite crucible which have broken loose coming in contact with the tools and sticking to them. Sometimes these blisters or beads drop off, leaving pits. The longer service the bath has seen the more loss is suffered through this blistering and pitting.

A graphite pot lasts only from six to eight heats, making this method of hardening quite a costly one. A new salt is now being introduced for the hardening of high speed steel, which can be maintained at a temperature of 2,200 deg. F. (1,204 deg. C.), thus being superior to the barium chloride bath. The container used is a graphite crucible with a cast-steel liner. In this way the steel pot is protected from the flame, and there is no danger of blistering or pitting from particles floating through the bath.

Pack Hardening

Pack hardening consists of packing the high-speed tools with charcoal in a suitable container. The container is then luted carefully with clay, and the whole placed in a furnace, the temperature brought up to around 2,200 deg. F. (1,204 deg. C.) and held there a considerable length of time. Tools are then removed, oil-quenched or air-cooled. This method gives a tool free of scale, but has the following decided disadvantages: (1) Quenching temperature is too low, and (2) tools are carburised. We obtained the temperature of some test-pieces with an optical pyrometer just before they were removed from the pack, and found the temperature to be about 2,050 deg. F. (1,121 deg. C.), although the furnace temperature was 2,200 deg. F. (1,204 deg. C.), and they had remained 1½ hours at heat. Scleroscope tests and micrographs verified this temperature. Furthermore, test pieces showed a gain of 0.40 per cent. carbon on the surface after being given the pack treatment.

I have been informed by two different men who attempted this method that at times the cutting edges of tools melted, due either to the higher carbon content of the surface of the tools or to the tools coming in contact with each other. One other experimenter tried to use a cast-iron box for packing, but as cast iron melts at about 2,200 deg. F. the results can well be imagined. Carborundum powder has been suggested as a substitute for charcoal for a packing material, as the former would not carburize the steel. In the writer's opinion, however, high-speed tools treated in this way would be inferior to tools heated in the semi-muffle furnace, because the steel would have to remain at a high temperature for a long time when pack hardened, thus producing a coarse-grained structure.

A lead bath was tried quite extensively about 10 years ago for heating high-speed tools, but the method did not prove a success. At 2,200 deg. F. the vapor pressure of lead is about 20 mm. of mercury, so that severe volatization will inevitably ensue. It is also quite a problem to find pots to hold the same. Difficulty is also experienced in controlling the time of immersion, as lead is a very rapid heating medium. A metallurgist for one of the large tool steel mills in England told me recently that a large amount of high-speed steel was hardened in his country by the lead bath treatment. He stated that they were able to obtain a very pure grade of lead and could operate at a temperature of 2,300 deg. F. (1,260 deg. C.). His method for hardening a 1-in. high-speed hand reamer would be to preheat to 1,500 deg. F. (816 deg. C.) in a muffle furnace, then transfer the tool to the lead bath whose temperature was 2,350 deg. F. (1,288 deg. C.,) hold there 15 seconds and cool in an air blast.

Most of the high-speed steel hardened in this country is heated in semi-muffle furnaces, oil or gas fired. It is always advisable to have these furnaces equipped with pyrometers, using Noble metal couples. The optical pyrometer is also satisfactory for controlling these high-temperature furnaces.

Work to be hardened should be preheated to 1,500 to 1,600 deg. F. (816 to 871 deg. C.), and when thoroughly heated through at this temperature, transferred to the high-temperature furnace, whose temperature is higher than the desired hardening heat. The tool is left in this furnace until the cutting edges have attained the proper temperature—about 2,300 deg. F. (1,260 deg. C.)—and the material then quenched. Soaking at the high temperature is to be avoided, as it coarsens the grain and is likely to "burn" the steel. In such practice the time factor is evidently just as important as the temperature. Quenched tools are then drawn to the desired temperature. One great advantage of this method of hardening is the high temperature attainable, thus producing the greatest degree of red-hardness and almost complete solution of the carbides. The disadvantage is that the tool scales to a degree, which can be reduced to a minimum by a thorough preheating and the proper mixture of fuel and air in firing the high-temperature furnace. Large high-speed tools have been very successfully hardened by using two preheating furnaces; the first is maintained at a temperature of about 1,100 deg. F. (593 deg. C.) and is used as a stock furnace. The temperature of the second preheater is 1,700 to 1,800 deg. F. (927 to 982 deg. C.). The material will not scale in the first preheating furnace; while the steel will oxidize in the second preheater, it requires less time to bring it to heat, thus reducing scaling to the minimum.

NEW COIN MAKING MACHINES

It is an interesting fact that almost every government in the world employs British-made coining presses in its mint. Recently the French government installed a set of fourteen presses of British make for the minting of nickel bronze coins to replace the two franc, one franc, and half franc notes which have been used during the war. These new presses are constructed to work at a high speed and are capable of turning out one hundred finished coins per minute. The presses are automatically fed with blanks of metal from a hopper and should the supply of metal fail from any cause they stop automatically, thus preventing the dies being injured.

How to Handle Work on a Magnetic Chuck

Principles of Heald Magnetic Chuck Explained—Many Operators Fail to Take Full Advantage of Valuable Points—Understanding of Simple Features Necessary—Better Results Obtained

MAGNETIC chucks consist of several electro magnets, constructed so that their ends or poles will come in contact with the work to be held and so hold it by magnetism. One of the physical properties of a magnet is its ability to attract and hold steel and iron pieces. It has two poles or ends, a positive and a negative pole, which is illustrated by the fact that when a positive pole of one magnet is brought near the negative pole of another magnet they are drawn together; but if it be brought toward the positive pole of another magnet they are repelled.

Magnetism

Theory explains magnetism by assuming that all matter is composed of very small particles called molecules. In a piece of iron or steel each molecule is assumed to be an elementary magnet, having a positive and a negative pole In an unmagnetized steel or iron bar, these molecules are not arranged in any particular position, and so neutralize each other, Fig. 1. However, they can be arranged so that they lie in the same general direction with their positive poles all pointing toward one end of the bar, Fig. 2. When in this position, the bar itself becomes a magnet with a positive and a negative pole.

The Electro Magnet

This last position of the elementary magnets of the iron bar can be obtained by means of an electric current. There are lines of force surrounding a wire through which electricity is passing, which will force these molecules in position. So by winding a wire around the bar, the molecules will arrange themselves in the same general direction, when the electric current is allowed to flow through the wire. In Fig. 3, such a bar is shown bent in a "U" shape, commonly called a "horseshoe" magnet. The dotted lines represent the magnetic lines of force which tend to grip the work.

Chuck Construction

This particular chuck consists of several of these electro magnets constructed so that their poles can be placed and firmly held by means of the magnetic lines of force. The top plate consists of a cast iron frame in which soft steel pieces are inserted. These pieces called "pole pieces" rest on the ends of the magnets and transmit the magnetic lines of force to the surface of the top plate.

In Fig. 4, the sectional view of the top plate shows the pole pieces which rest on the magnets in the chuck body. The poles of these magnets alternate plus or minus, or positive and negative, and the lines of force are indicated by dotted lines. These you see radiate from pole piece to pole piece.

These pole pieces or poles are insulated from the cast iron top plate frame by non-magnetic metal, so that the magnetic lines of force will not escape into the top plate frame instead of going into the work. Pieces of work are also shown in position and the lines of force are seen entering the work and holding it. Since the force with which work is held on the chuck depends upon the number of these invisible lines of force which enter the work, it is evident that the work must reach from pole to pole and that it bear on the poles as closely as possible, for if there is an air space between the work and the poles, the lines of force will be greatly weakened. The resistance of air is 100,000,000 times as great as in iron or steel, which emphasizes the need of the work bearing on the poles.

Proving a Theory

To prove this take a rough crooked piece of steel and another piece of the same size but smooth and straight and see how much firmer the last piece is held. Now lay a piece of steel about ¼ in. square and long enough to reach across two poles, then lay it between two poles and then on top of a single pole and notice it is not held so firmly as when it lies across two poles. The greater part of the holding power of the magnets is perpendicular to the surface of the chuck. Therefore, on heavy operations, the "End Stop" and "Side Bar" are used to counteract the push of the cutting tool.

Since the work must have as much contact with the magnetic poles as possible to be held firmly, auxiliary means must be provided to transmit the magnetic lines of force to work which does not offer much bearing surface. Fig. 5 shows how many users have incorrectly tried to do this by means of a steel plate with recesses cut in it so it will fit the contour of the work.

This method is not successful, for the magnetic lines of force find an easy path through the steel plate and do not go into the work. On the right the correct method is illustrated. Here the pole pieces of the auxiliary top plate carry the lines of force into the work.

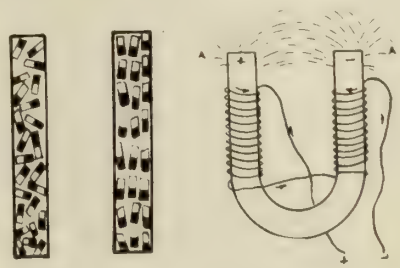

Fig. 1. left—Position of molecules in immagnetized bar. Fig. 2. centre.—Position when bar is magnetized. Fig. 3.—Common horsehoe magnet.

The Auxiliary Top Plate

The plate is a duplicate of the standard top plate of the chuck, except slots or recesses are machined in it to make it fit the work so that there will be a perfect bearing for the work to lie on. While the recesses might be cut in the standard top plate, it is not recommended, as it is apt to open up the joints between the pole pieces and allow water to leak in the chuck and cause the coils to burn out. There again the standard top plate would not be good for other work, while by using the auxiliary top plate it can be removed and another one substituted, or flat work held directly on the top plate.

The auxiliary top plate is fastened to the chuck top plate by bolts and care must be taken that its poles rest directly on the poles of the chuck top plate. It must be drawn down tight so that there will be no air space between the two plates.

By using auxiliary top plate all shapes of work can be handled. Sometimes simple fixtures will help. In every case where a filler piece must reach across two or more poles, it should be made of hard brass, or any non-magnetic metal, so as not to weaken the magnetic lines of force.

This applies as well to retaining rings and locating pieces frequently used with rotary chucks on lathes and universal grinders.

Demagnetizing Work

All standard chucks are equipped with demagnetizing switches, which demagnetize the chucks so that the work can be easily removed. Referring to Fig. 3, you see the current is flowing in one direction; the demagnetizing switch reverses this current when the

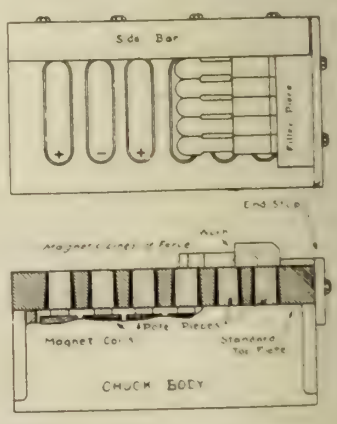

Fig. 4.—Plan and section of chuck.

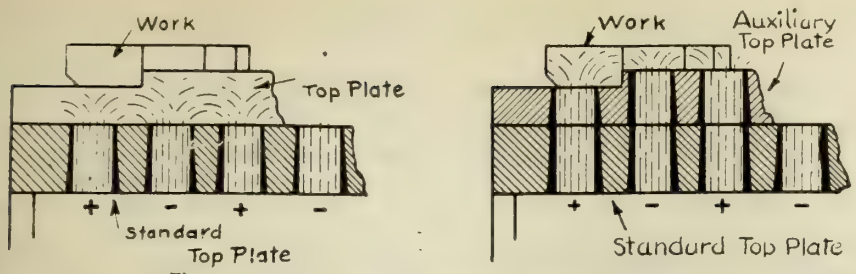

Fig. 5.—Old and improved method of making top plate.

handle is thrown back, so that the molecules are forced to change their position. The current, however, should not be allowed to flow in the reverse position only an instant; otherwise the molecules will again arrange themselves in position in the opposite direction.

The demagnetizing switch demagnetizes the average work, but hardened steel and very large pieces give up their residual magnetism reluctantly. Therefore, a demagnetizer is needed to neutralize the molecules. This is really a from of a simple magnet which continually reverses its polarity rapidly. This reversal is caused by alternating current, which continually changes its direction. It is readily seen that, if the current in the magnet of Fig. 3 changes its direction many times a second, the molecules will be thrown out of any fixed position.

POINTS TO REMEMBER

The greater the area of contact the work makes with the magnetic surface the stronger it is held.

Work must touch at least two poles to obtain greatest possible holding power.

Most of the holding force acts perpendicular to the face of the chuck. So when they will cross two or more poles, use end and side bars on heavy cuts.

Don't use iron or steel filler pieces as this weakens the pull. Use non-magnetic material.

Use auxiliary top plates instead of machining or drilling the standard top plate.

Auxiliary top plates must bear evenly on the standard top plate.

The pole pieces of auxiliary top plates must line up with those in standard top plate.

Do not use a chuck top plate after it gets too thin, it may leak water.

Magnetic chucks operate on direct current only.. Alternating current cannot be used.

Direct current drops in voltage if the feed wires are too small and if chucks are located too far from generator.

In case of trouble be sure to see if the required number of volts indicated on chuck name plate are entering the chuck. Make your test as near chuck as possible.

Don't jerk demagnetizing switch, work it quickly but smoothly.

Do not take chucks apart.

Analyze Different Phases Of Factory Profits And Costs

MOST of us if asked to define the word profit, as applied to the business activities of a machine shop, would consider the question almost too elementary for consideration. But do we really understand the term when it is expressed in percentages? In Fig. 1 it is shown how deceptive the term really is. It is capable of being expressed in percentages varying between 7½ and 20. Take the case of a factory whose net profit is $15,000. To qualify the figures in Fig. 1, the cost of operation would be $75,000, the total sales $90,000, and the investment $200,000. In attempting to reply to the question as to which would be the proper way to express the profits, it must be admitted that a difference of opinion exists. The total sales, or turnover, for the year, represents the gross income. If the gross cost of operation be deducted the difference is the profit and it is usual to express the profit as a percentage of the gross receipts. If the shop is owned by a joint stock company, the stock holder is most interested in knowing what percentage the profits will earn him as dividends. It is a question that must be carefully understood and when understood it is quite permissible to refer to the profit as a percentage of any of the three figures mentioned.

Another angle on costs is to break them up into component parts. To most of us the word "cost" conveys a more or less definite idea of what is referred to. In the case of machine shop activities, if we are to fully appreciate costs, we must break up the lump sum into its component parts. Graphical representations of two sets of cost figures are shown in

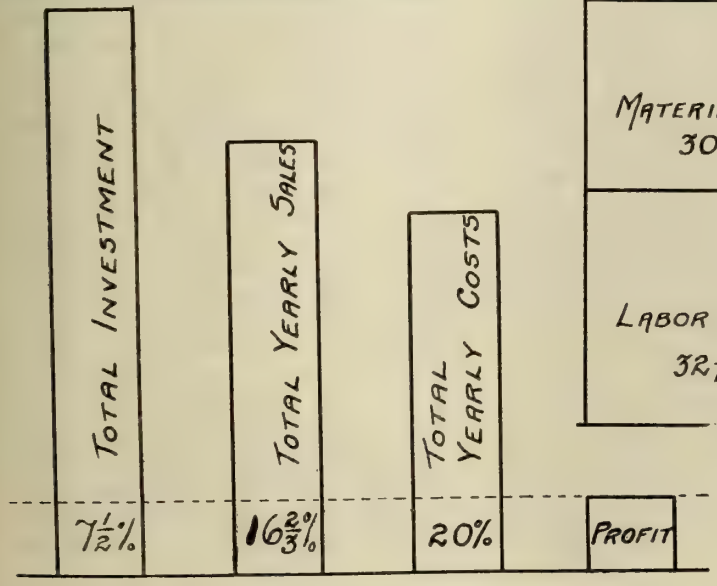

Fig. 1.—How can we measure it best?

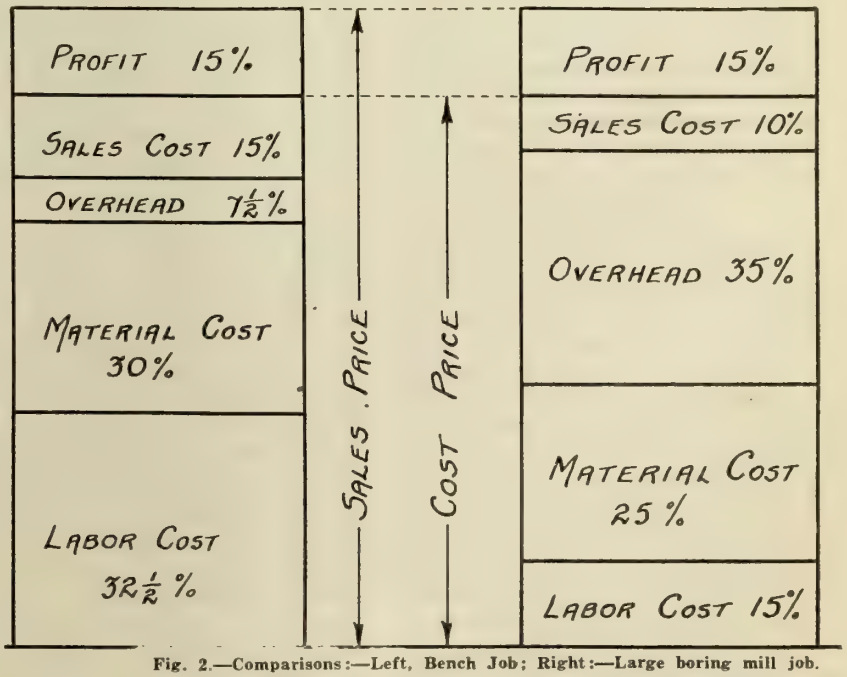

Fig. 2.—Comparisons:—Left, Bench Job; Right:—Large boring mill job.

Fig. 2. In the case of the bench job the labor cost represents a relatively high percentage of the sales cost, when compared to the large boring mill job. The cost of material is always a variable, because in the case where a simple iron

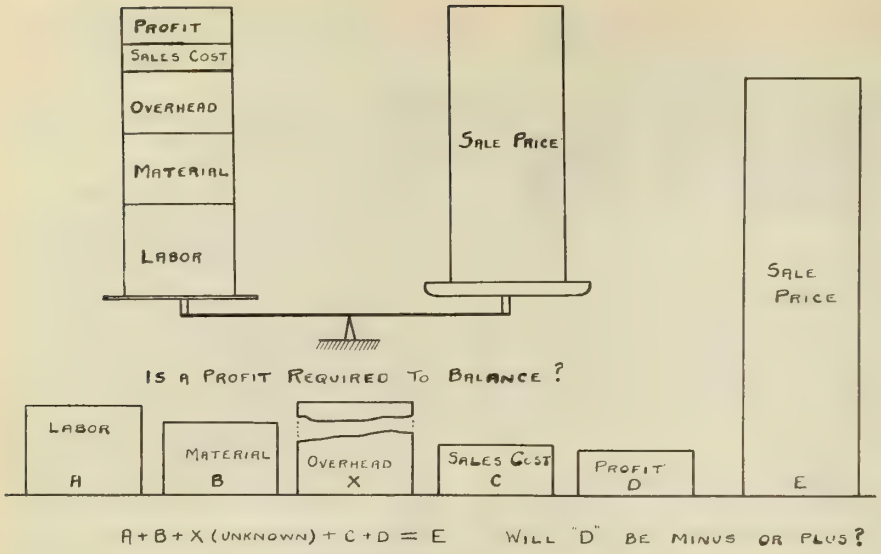

Fig 3—Two views of a question

casting is used it may be comparatively small, then again an intricate brass casting or a difficult forging may be the material required, and the cost is naturally greater, and represents a larger percentage of the sales figure. The overhead charges are also rather difficult to define, and at times are hard to determine. Actual overhead, that can be more or less directly attributed to a bench job, is not large, but at the end of a year indirect charges, in addition to direct overhead charges, would have to be borne by that particular class of work. On the other hand, direct overhead charges, in the case of a boring mill job, constitute quite a formidable item. Sales costs run somewhat higher as a general rule when small products of a machine shop are marketed, than when larger articles are disposed of. Thus in making up estimates on the probable cost, executives must be careful to view the work not only from the financial standpoint, but also from the shop viewpoint.

Fig. 3 is an attempt to graphically represent the relationship between the overhead factor of cost, and profit. Books must be balanced, and the term "balance" suggests a weighing scale. In the case where a selling price is fixed, the item of cost must be below that figure, if a profit is required to "balance." Both sides of the equation must balance, and in Fig. 3 the overhead is represented as an unknown quantity. The selling price is assumed to be fixed. Now if the "unknown quantity" can be kept down sufficiently, the profit will be positive, or plus. If the overhead soars, the profit must naturally become minus, as the equation must balance. A minus or negative profit is nothing other than a loss.

The foregoing suggestions may offer a new viewpoint to many who are to-day struggling along at a great disadvantage in these times of so-called depression. In machine shop practice the cost is an unusually complex item and there are few lines of endeavor that create such a problem in making up estimates.

EFFICIENT ANNEALING OF MALLEABLE CASTINGS

In reply to a question recently appearing in the transactions of the American Society for Steel Treating, on "What is the shortest time in which malleable castings can be annealed to produce the best malleable qualities?" H. A. Schwartz, manager of research, National Malleable Castings Co., Cleveland, gives the following:—

A strictly correct reply would probably be infinity since, speaking broadly, every means of accelerating graphitization is detrimental to the ductility of the product. A strictly logical conclusion thus would indicate that the slower the process the better the product, hence the best product can be made only in infinite time. Graphitization proceeds more rapidly and less completely the higher the temperature. Its commercial execution is accomplished by holding the metal for a time at a temperature well above A_1, and then cooling in such a manner that the metal shall be at or near A_1 for a sufficient time to complete the reaction.

Time will be saved by executing the preliminary treatment at the highest practical temperature. However, the higher temperature the coarser the temper carbon granules and the less strength and ductility, consequently there is a limit to the time to be saved by raising the initial temperature. Commercial opinion varies as to the highest safe temperature. Some manufacturers feel it unsafe to go above 1,500 degrees Fahr.; others go as high as 1,850 degrees Fahr. The former makes for quality, the latter for speed. A temperature of 1,600 or 1,625 degrees Fahr. is perhaps a conservative middle course.

Commercial practice varies with respect to the completion of the reaction. Some metallurgists cool slowly through the critical range; others feel it better to maintain a constant temperature just below A_1 for some time. The latter course, no doubt, saves time but requires very accurate control to avoid passing above A_1 by accident. Graphitization can be accelerated by an increase in carbon or silicon, both of which deteriorate the quality of the metal when present in too large an amount. Here again speed is had at a sacrifice of quality.

In the early days, using carbon and silicon in amounts now considered excessive, it was very common to occupy 7 days for the annealing cycle. The recent improvements in malleable castings were accomplished in part by reductions in carbon and occasionally silicon and by greater annealing precautions. The time for annealing has thus risen for two reasons. The writer has frequently annealed metal in small commercial furnaces in 3½ to 4 days. The metal was never of superior quality and frequently very unsatisfactory and this attempt to hasten deliveries was definitely abandoned.

The design of heating furnace also affects the answer since uniform rapid heating is difficult to attain in large furnaces; but such furnaces are economical of fuel and space. Under commercial conditions and on an operating scale, the writer would regard with suspicion metal annealed in less than 7 days and would not regard 10 or 11 days as excessive. Where particular importance is attached to ductility and to machine-ability, without sacrifice of strength, still longer times may be called for. A single piece, of inferior quality, could no doubt be produced experimentally in around 50 or 60 hours.

STAMP TAX PROBLEMS

In actual operation, the new stamp tax is revealing some objectionable features which may have to be remedied. A case in point is that supplied by a wholesale grocer in London, and is likely to have frequent repetition. In this instance the wholesaler drew on a customer to the amount of a bill of goods, the sum being about $600. The draft required 24 cents in stamps. The customer returned the draft because it was not convenient to pay, but in the meantime it had been discounted and it was necessary to issue a cheque to the bank to cover the amount. Thus another 24 cents was required in taxes. Thus the company paid 48 cents taxes on a deal that actually did not occur, and when the time comes again for payment of the postponed obligation the taxes will be called for a second time by the government. Though the amount is small, merchants object that such payments are a hardship in transactions where the margin of profit is limited.

After forging high speed steel it is always advisable to anneal it before hardening, as residual forging and cooling strains may cause breakage in the hardening process.

Iron and Steel in the Cement Industry

Stresses on the Crusher Shafts—Cause of Breakage—Proper Heat Treating Essential—Failures Generally Due to Physical Faults—Engineer Should Co-operate With Plant Metallurgist

BY W. R. SHIMER

THE WRITER cannot claim to be familiar with the mechanical details of cement machinery, and is, therefore, not in a position to ascribe failures to faulty design, although from an examination of certain failed parts there is every indication that some of the failures can be attributed to error in design. For example, the writer had the opportunity to investigate the breakage of shafts in an electrically-operated shovel. This shovel was operated in the same quarry with two steam shovels. No shafts were known to break in either of the steam shovels, while the shaft breakages in the electric shovel were quite frequent. The writer was called in on this matter after the cement plant had proven to the engineer who built the shovel that power was developed which stressed the shaft to a load of twice that for which it was originally designed. In other words, when the electric shovel was attempting to dig out the side of a hill in one scoop, and since an electric motor will withstand a 100 per cent overload momentarily, the shafts were stressed to double the amount for which they were designed, and as this stress was a sudden one, the shafts naturally twisted off. I understand that when a steam shovel is over-stressed, it will stall; there are no sudden shocks, and consequently shaft failures are much less frequent in shovels of this type.

Shaft Specifications

The shafts in the electric shovel could not be made larger without making very radical changes throughout the entire mechanism, and it was, therefore, necessary to use a special nickel chrome steel, heat treated to give more than twice the elastic limit of the original shafts, and at the same time, the elongation and the contraction of area had to be fairly high to insure sufficient ductility to withstand the usual shock and vibration. The physical properties of the failed shafts showed approximately the following:

Tensile Strength	62,000
Elastic Limit	32,000
Elongation, per cent.	35.5
Contr. of Area, per cent.	61.07

The heat treated alloy steel shafts showed:

Tensile Strength	112,000
Elastic Limit	90,000
Elongation, per cent.	22.5
Contr. of Area, per cent.	64.0

These physical properties more than make up for the deficiency in the size of the shaft. It might be of interest to mention in this connection that for quick repairs, cold drawn shafting was used for shafts in this shovel, and some broke in one week's time.

Cold Drawn Steel

While on the subject of cold drawn steel, I might mention its properties and the object in using it. It is made by pickling all the scale from the hot rolled bar, which is then pulled through a die 1/32 to 1/16 in. scale less in diameter than the original bar. This produces a bar of accurate size, with a smooth, bright finish. The bar is reduced cold and while cold extends in length in proportion to the amount of reluction in cross section. Low carbon steel is cold drawn without annealing but the higher carbon and alloy steels are annealed first. The physical effect of this cold working is to raise the elastic limit, in the smaller diameters, up to approximately 90 per cent. of the ultimate tensile strength, with a corresponding decrease in ductility. Prior to cold drawing, the elastic limit of the same steel approximates 50 per cent. of the tensile strength, with considerable ductility. I would not recommend that cold drawn steel be used for important structural parts which must withstand shock and vibration. It is an excellent steel for screw stock, bushings, sockets and parts of this nature which must be turned out cheaply by the thousands on automatics. It is satisfactory for line shafts and other parts of like nature which are not highly stressed. Some years ago an automobile company in an attempt to save money on lathe work used, for a time, a cold drawn alloy steel for axles. They were drawn to finished size, and all the machining that was required was to cut to length and mill the ends square. This proved to be expensive economy as these axles failed in many of the cars after short service, and replacements were made free of charge in order to satisfy the car owners. The replacements were made of a special heat treated alloy steel, and they returned to the practice of turning the bars on a lathe rather than to obtain the accurate size by cold drawing.

Cold drawn steel has its field, and I do not wish to be misunderstood in my remarks concerning it. It is, however, false economy to use it for highly stressed parts, as there are so many steels which can be heat treated to stand up under severe service and which will far outlive cold drawn steel.

Proper Heat Treatment

Many parts fail in cement machinery on account of not being heat treated, or having been improperly heat treated for the service to be performed. Many times steel of correct composition for a certain use fails in a very short time, because of improper heat treatment. When properly heat treated this same steel will give satisfactory service. As a concrete example of this, I will cite the case of an order we received some years ago for ten bars of nickel steel four inches in diameter. This order was received from a drop forge concern and from the composition of the steel ordered, it was inferred that the steel was to be cut up and forged into gear blanks, which were to be subsequently heat treated. This steel was, therefore, shipped to the customer in its annealed condition, having been annealed for machinability. A short time later, we received a complaint, stating they had made piston rods from three of these bars and put them in drop forge hammers. One lasted 2½ hours and broke, another lasted 5½ hours, and the third lasted about 15 hours. They stated this so-called high grade nickel steel was inferior to brass or wrought iron. The remaining seven bars were returned and given a special heat treatment by quenching in oil, with subsequent annealing, and were returned to customer and were found to be entirely satisfactory. This is one of the many examples which could be cited to show that while steel properly heat treated is satisfactory for the service required, steel of the same heat but improperly heat treated is not satisfactory. I might mention that in order to obtain the best service from alloy steels, they must be heat treated, as it is not good economy to use them otherwise. When heat treated, they are far superior to ordinary steels.

Proper attention is not always given to steel castings, due in part perhaps to the users feeling that because the casting was made of steel instead of iron that it had all the strength that was required, with the result that no check was made as to the analysis of the steel, or to its annealing. This applies, of course, to commercial castings. There have come to my attention quite a few failures of machines where steel castings have been used. The machines in mind at the present time are large jaw crushers.

Designing Crushers

Up to a few years ago, the primary crusher was fitted with a jaw opening of about 24 by 36 inches but with the advent of steam shovels, it became necessary to increase the size of crushers

with the result that these machines are now built with openings up to 5½ by 7 feet. In the designing of these larger size crushers, the manufacturers went to the use of steel and made a great many of the crushers in sectional design, i. e., the side frames and end frames being separate castings, machined and held together by turned bolts.

Another design of crusher consists of a "semi-steel" frame reinforced with a cast steel band which is shrunk around the bottom of the frame and a cast steel band around the top. The design of this crusher is such that the steel bands take all of the crushing strain. The failures of these steel crushers have been due partly to the fact that the analysis of the steel was incorrect, and partly to the fact that the castings had not been properly annealed, if annealed at all. In one of the large plants, not so long ago, there was broken in operation a crusher in which the frame was 20 feet long and the cross section of the steel about 6 inches by 5½ feet. The breakage of these castings showed that the steel was very coarse grained and that it had not been properly annealed, with the result that original strains were still in the castings. Had these castings been properly annealed, there is no question but that the machine would have stood up and that the breakage would not have occurred. The repairs to this particular machine will cost the operating company many thousands of dollars, as the machine will first have to be banded together to permit it to continue to operate, and later the side frames entirely replaced with new castings.

Failure of Parts

There has also been brought to my attention the failure of a crusher which was reinforced with a heavy steel band. This band was of oval shape and had a wall cross section of 5 by 24 inches. It broke at three points almost simultaneously, and the nature of the breaks indicated brittleness. Upon investigation, it was found that the casting was too high in carbon and further that it had not been properly annealed. The microscope showed a structure of steel in the same condition as when cast, and if it had been annealed at all, it only went through the motions of this operation, as there was no indication whatever of annealing from the examination of the casting itself.

Foundries or forge plants will often, in order to fill up their shop, take on work for which they are neither trained nor equipped to handle. Sometimes, by good fortune, their product stands up in service, but in many cases like the one just cited, it did not, and caused considerable loss to the cement plant and considerable embarrassment to the crusher manufacturer, who was not directly to blame. Manufacturers of machinery should, however, investigate the foundry prior to placing orders for castings, to determine if they are competent to make such castings, and the castings should be inspected to be sure they are of the right composition and properly annealed.

Taking Physical Tests

The practice generally followed is to specify certain physical properties in accordance with the specifications of the American Society for Testing Materials. These tests being taken from coupons which are attached to the casting, and heat treated with the casting. Test coupons are integral with the casting. They should not be broken from the casting until it has been heat treated. If, by accident, the coupons should be broken off prior to annealing, they should not be heat treated separately but should be charged in the same annealing furnace at the same time with the casting in order that it receive identical heat treatment with same. This is necessary in order to be assured that the physical results obtained from the coupon represent the physical properties of the casting itself.

Failures such as those just briefly cited might mislead prospective purchasers into believing the machinery itself was at fault. In cases of this kind, no reflection can be cast upon the make or design, because the failures are directly due to the fact that the makers of the castings did not furnish a good product. It is always unwise to place an order for a special part to the lowest or any bidder, without first having been satisfied as to his ability to furnish a satisfactory product.

The average mechanical engineer knows steel only in a general way, as he has neither the time nor the opportunity to keep up to date with the rapid advances made in this art. Even we, who are working on this subject all the time, find it difficult to keep pace. An engineer will design a part and figure on a certain factor of safety, for example of 5 to 1, when he expects to encounter shocks, etc. With this factor of safety, he may require steel of say 110,000 lb. elastic limit, which predetermines an ultimate strength of approximately 140,000 lb., but loses sight of the fact that to meet this high elastic limit, the elongation and contraction will be relatively low, and he will have a steel lacking in ductility, so that the real factor of safety is actually much lower. For such a highly stressed part, he would have a more satisfactory product if he used a factor of safety of 4 to 1, and asked for a steel having, say 90,000 lb. elastic limit, with proportionately lower tensile strength, since he would have a corresponding increase in ductility, thereby enabling the part to withstand shock and vibration.

One big problem in some cement plants is to obtain satisfactory shafts for gyratory crushers. Low to high carbon steels and alloy steels heat treated for high tensile strength and elastic limit have been used, but certain plants still have more breakages than they should. I have been investigating this subject with a view to developing a satisfactory steel and a heat treatment for this purpose. In general, I find the tensile properties need not be high, but the important properties are elongation and contraction of area. The shafts which on the average stand up longest in service are those with greatest ductility.

Reason for Shaft Breakage

On interviewing a number of cement plant operators who use the gyratory crushers it has been found that such shaft failures are peculiar to certain plants, while others rarely if ever have this trouble. The plants which have no failures attribute their success to the fact that they make a special effort to keep dipper teeth, sledge hammers, and other iron and steel parts from going through the crusher. The penalty to employees allowing such parts to go through is dismissal. I am inclined to believe that this is one of the major reasons for shaft breakages as this would explain why the harder shafts are more susceptible to failure than the softer and more ductile ones. When a large piece of steel passes through a crusher, something has to give, as the crusher itself cannot stall. If the liner plates do not break, the shaft must distort. A hard shaft will act as a spring, but the excessive strain which has been put on some points, usually on the outside surface, will produce a nick of perhaps microscopic size, which we might call an incipient break, and during continued service, it grows larger, finally resulting in the fatigue break, which these shafts manifest on fracture. The softer steel shafts will bend and at times even take a permanent set, but there is no doubt but that the increased ductility accounts for their being longer lived. When a plant has an unusual number of breakages of this nature, and if it is certain no foreign material has gone through the crusher, an investigation should be made by a competent party, as such a condition can generally be corrected either by a change of steel or by special treatment. Some gyratory crushers are being redesigned in order to permit shortening of these shafts, and these shorter shafts are reducing the breakages to a considerable extent.

It is easy to imagine how the cement plant engineer, or the engineer building machinery, who might interview six to a dozen representatives from as many different steel concerns, could become confused when attempting to boil down the diversified information received. The same thing would happen if the writer were in the market for cement, and with his limited knowledge of this product, would have difficulty deciding whose cement was best after interviewing representatives from as many cement companies. I would probably purchase from the lowest bidder, and no doubt obtain just what I paid for, namely, an inferior product. The enthusiastic steel salesman may elaborate on the wonderful physical properties of a special alloy steel, representing results obtained

from a small test bar, and leave the cement engineer to believe that these results can be obtained in a 15 or 20-inch diameter forging. Were the engineer to attempt to purchase a forging requiring such high properties, the reliable steel manufacturer would try to discourage such requirements, but the engineer might find some one hard up for work who would try to furnish it, and the chances for its giving satisfactory service would be very slight.

It is safe to state that cement machinery must stand as much or more abuse than machinery for most other industries, on account of the abrasive materials handled, and the considerable amount of dirt and dust always found in the cement plant, which becomes imbedded in bearings. Some parts must stand both wear and shock, and some must stand either shock alone or wear alone. In the case of parts which must stand both wear and shock, a happy combination can be obtained by means of case hardening the outside surface, which will resist wear, retaining a strong and tough core to resist shock. In the case of a part which is not subjected to shock, this can be made of a steel which can be hardened throughout. In the case of a part which must stand severe shocks and vibrations, certain steels can be specifically heat treated to stand up for this service. It is my impression that certain parts, such as gudgeons, liner plates for tube mills and crushers, are expected to wear out in a certain length of time, and replacing material is ordered without investigating the possibility of obtaining a material which will give double the service or better. It seems that breakages and excessive wear are accepted as a matter of course by many cement plants. There are manganese steel castings made which stand up best under certain conditions at one plant, while some other special steel casting or forging will give better service at another plant. Each plant has its own individual problems which can be worked out by the proper co-operation with reliable steel manufacturers.

Take pinions, for example. Cast iron pinions are cheapest if the first cost is considered only. Occasionally a cast iron pinion makes an exceptional record, but how often is a cast iron pinion obtained which wears out or breaks in a short time, usually breaking before being worn out, and where the cost of labor and curtailment of production on account of repairs would make the ultimate cost considerably higher than if good special steel, heat treated pinions had been purchased in the first place.

Obtain Full Details

Satisfactory iron or steel for almost any purpose can be obtained if the manufacturer is acquainted with full details concerning requirements, and if he is paid the price. No matter what the commodity is, we generally receive the quality we pay for. When a cement company wishes a forging and is only willing to pay a certain limited price per pound it will receive a forging which is worth the price paid for it and no more, since in order to make a forging at such a figure the steel manufacturer will have to select his steel accordingly, and perhaps at this price he cannot afford to heat treat it. If a forging is required, payment of a fair price to a reliable manufacturer will secure a special steel properly selected, and will insure careful heat treatment for service required. Though such a forging might cost three times as much per pound, it would probably last more than three times as long; but if it outlives the lower priced forging 2½ times, it would be cheaper in the end, on account of continued operation during this extended period and saving on cost of taking down and reassembling.

In the case of the steel casting failures on the jaw crushers, mentioned earlier in this paper, these castings would no doubt have been cheap at 50 cents a pound if they had not broken.

The cement engineer should work closely with the steel plant metallurgist and the cement plant purchasing agent should work closely with the cement engineer. In cases where the purchasing agent does not co-operate with the engineer, he will buy steel other than that specified by the engineer if he can obtain a reduction in price. This reduction in price may be quite costly, due to curtailment of production and cost of repairs on account of break-downs.

If there are parts which break or wear out too soon, the cement plant should look for something to give better service and go to a reliable source of supply, state what is wanted, with a complete history of the average service obtained from past material, and details of its iron or steel composition. With such information, the metallurgist should be able to recommend iron or steel which would be more satisfactory, and while many times he may recommend a steel which will cost somewhat more, sometimes he finds a high priced steel being used where a much cheaper steel would have given as good or better service.

Importance of Co-operation

It is necessary to emphasize the importance of co-operation between the cement engineer or the engineer building cement machinery, and the steel plant metallurgist. In our corporation, we find it valuable for our plant engineers and engineers who are designing or building machinery to keep in constant touch with our metallurgical departments. When they design a machine to perform a certain operation, they first consult the metallurgists to determine which steel will best stand up in service, and the physical properties which can be obtained from this steel, and they then design their machinery accordingly. In some plants the designing engineer will design his machinery independent of metallurgical advice and make some parts so light and at the same time requiring extremely high physical properties, that he works a hardship on the metallurgical and heat treating departments which must resort to the use of high priced alloy steels, which may be very sensitive to heat treatment, and which may crack and distort during the drastic heat treatments needed to obtain the extremely high physical properties. This results in high shop losses and often in the installation of defective parts, causing failure in service. Where there is close co-operation between the engineer and metallurgist, such a condition is not likely to occur, and although the machinery may be somewhat heavier, it will be more efficient. The metallurgist finds it necessary many times to consult with the engineer before recommending steels for certain parts in order to become acquainted with the exact details of the duty which the particular parts are to perform. We find in our corporation that neither can get along without the other, and certainly this same condition must hold true with the cement industry or any other industry using iron or steel.

PROGRESS OF STANDARDIZATION WORK

(Continued from Page 22)

and has in preparation many other important specifications.

The Association is now endeavoring to arouse Dominion-wide interest in the matter of safety codes as affecting public safety in such important connections as elevators, saw-mills, machinery, electrical work, etc., with a view of organizing a thoroughly representative committee and bringing persuasion upon the various provincial governments in order to unify their requirements and remedy the present unsatisfactory conditions. In this work there is no doubt that the results of the activities of the two American Committees dealing respectively with the National Electric Code and the National Electric Safety Code, will be fully considered and appreciated.

Much of the Safety Code work now being actively pressed forward in the United States is of great interest to Canadian industry and in many cases we have received cordial invitations to co-operate, which have been greatly appreciated.

IGNITION OF COAL DUST BY ELECTRIC ARCS

The extensive use of pulverized coal for fuel in industrial plants gives interest to tests recently made by the United States Bureau of Mines, which proved that coal dust suspended in air can be exploded by electric arcs under conditions that might prevail in a pulverized coal plant or in a coal mine. If there is electrical machinery in places where coal dust is apt to collect in quantities capable of producing a dust cloud, such electrical machinery should be housed in compartments designed especially for use in dusty atmospheres. Under Schedule 2B, the Bureau of Mines is prepared to conduct investigations.

Lathe Dial Screw Thread Indicator in Practice

Device Must Be Properly Understood—Application When Cutting Bastard Threads—Relative Movement of Dial and Threads Being Cut—Cutting of Fractional Pitch Screws

By HUBERT BENTLEY, A.M.I., Mech. E.

THE DIAL screw thread indicator now fitted to the majority of high class and medium size lathes is an exceedingly useful device when intelligently employed. If it is not properly understood, the probability is, that it will be removed from the lathe and the operator will resort to the old chalk mark method. Again, some operators may successfully employ the dial, working to the instruction chart, but not appreciating the limits of its usefulness, may condemn the attachment because they find it is not applicable to the cutting of a bastard thread. The purpose therefore of these notes is to make clear both the construction and the application of the dial screw thread indicator, so that it may be used intelligently when screw cutting.

Fig. 1 shows two views of a thread indicator attached to the carriage of a lathe by two hexagon-head set screws. There are four principal parts, the bracket, the dial, the vertical shaft, and the worm-wheel. The slot holes provided in the foot of the bracket allow the whole arrangement to be moved out of gear when it is not in use. In some designs, the bracket is made to hinge so that the worm-wheel can be swung out of mesh with the leading screw, when not required. When in use a spring device keeps the worm-wheel in gear. A dial, as shown in Fig. 2, is pinned to the top of the vertical shaft, and this generally has 16 divisions. The worm-wheel keyed to the bottom of the vertical shaft is cut to suit the lead-screw thread, and this should either have 16 or 32 teeth, according as the leading screw has two or four threads per inch.

Catching the Thread

Briefly, the thread indicator is a device used when screw-cutting, to enable the operator to catch the thread at the commencement of successive cuts, or to show when the screw to be cut and the lead-screw are in register one with the other. The pointer, or index mark, on the bracket must be made to coincide with one of the division lines on the dial when the half-nuts are in mesh with the lead-screw. This of course, refers to the preliminary fixing of the device on the machine. By using the thread indicator the old-fashioned chalk mark methods are dispensed with in the majority of cases, and there is no necessity for a reversing countershaft. The carriage can be traversed back by hand and the half nuts engaged at the critical point without fear of cross-threading. One revolution of the lead-screw (with the half-nuts disengaged), taking this as single-threaded, which is generally the case, would cause the dial to make a sixteenth of a revolution, or one division (see Fig. 2) if the worm-wheel had 16 teeth. With 32 teeth in the worm-wheel, the dial would make a thirty-second of a revolution, or half a division, so that two revolutions of the lead-screw would be necessary to move one division on the dial.

With the change wheels or feed-box gears arranged correctly for the screw to be cut, it is necessary to make engagements with the half-nuts at certain points only, to ensure the coincidence of the tool in the thread. These points, of course, depend upon the ratio of the threads per inch in the screw to be cut and the threads per inch in the lead-screw, or the ratio of the change-wheels, and occur when both work and lead-screw have made a whole number of revolutions. For example, if 15 threads per inch, it should be stated that lathe having a two threads per inch lead-screw, the work would have to rotate 15 times and the lead-screw twice, from being in register to coming in register again, i.e., in the ratio 15 to 2. Before proceeding to consider how the dial operates when cutting various threads, we must carefully observe that for cutting bastard threads, threads containing odd fractions, diametrical pitch threads, etc., the thread indicator can be used only if a chalk mark is placed on the work when commencing the cut, and adopting some division on the dial, say No. 1. The half-nuts must be re-engaged only when the No. 1 graduation and the chalk mark come into register. It must be understood however, that these are the unusual jobs, the indicator being applicable without the aid of chalk marks, for use in the majority of cases, as will be seen by the various examples which follow.

A lathe with a lead-screw having two threads per inch, a dial as in Fig. 2 and a worm-wheel with 16 teeth will be considered.

If the threads per inch in the screw to be cut are an even number, such as 2, 4, 6, 8, etc., the ratios per inch in the screw to be cut, to the threads per inch in the lead-screw, are 1 to 1, 2 to 1, 3 to 1, 4 to 1, and so forth. That is, for every complete revolution of the lead-screw the work will have made 1, 2, 3 or 4 revolutions, and the half-nuts may be engaged at this point and the thread caught correctly, one revolution of the lead-screw moving the worm-wheel one tooth, or 1/16th of a turn, i.e., 1 division of the dial. Thus the half-nuts may be engaged when any of the graduation marks on the dial are opposite the pointer, when an even number of threads per inch is being cut.

Cutting Odd Threads

Where the threads per inch to be cut are an odd number, such as 1, 3, 5, 7, etc., the ratios of threads per inch in the screw to be cut to the threads per inch in the lead-screw are 1 to 2, 3 to 2, 5 to 2, 7 to 2, and so forth. The work will have made in the respective cases 1, 3, 5 and 7 revolutions, while the lead-screw has made 2, and register is obtained, and the half-nuts may be engaged. In this case, the lead-screw has to make two revolutions that is, two divisions on the dial. Therefore where a screw having an odd number of threads per inch, is to be cut, the half-nuts may be engaged at alternate or numbered divisions on the dial.

Cutting Fractional Threads

When cutting fractional threads, if the fraction includes ½, say 1½, 2½,

Industrial Application of Ball Hardness Test

Reliable Means For Testing Metals—Classification and Control of Various Alloys—Eliminating Possibility of Error Due to Inexperience of Operator—Observations on Test

THE importance of the ball hardness test and its wide application to all branches of the engineering industry are not yet fully realized. As a reliable means for testing metals, controlling heat treatment and the rapid testing of repetition work such as castings and forgings, where it is impracticable to apply the more extended tensile tests, the Brinell hardness test is particularly applicable.

With the inception of the small ball hardness testing machine and power operated hardness testing machine the scope for the application of the test was considerably increased.

With the object of giving fullest information for the efficient working of these machines, the publishers of The Machine Tool Review have just issued a comprehensive booklet, entitled, "The Industrial Application of the Ball Hardness Test."

The matter comprises four sections, the first section giving the title to the booklet, the other sections dealing with:—

Machines for making the test.

Observations on the ball hardness test; and

Brinell hardness number tables.

A brief survey of each section is appended to give an idea of the comprehensiveness of this booklet.

Industrial Application

The Brinell test for the hardness of metals was introduced in 1900, and is now widely used both in the laboratory and the workshop.

Its many applications may be summarized as follows:—

Tensile tests may be displaced by the ball hardness test, as the hardness number follows very closely the tensile strength in steels of the same type. For repetition work the ball hardness test is therefore particularly suitable, and where steels are used in considerable quantities a chart may be prepared for each kind of steel, showing its properties, the Brinell test then giving all the information required to denote the use to which the steel may be put and also its machining qualities.

Much trouble may thus be saved in the machine shop, where batches of stampings have to be machined as a first operation after heat treatment, by first applying the Brinell test to ensure uniformity. Heat treatment can easily be controlled by placing certain Brinell limits on the steel, any deviation from these limits being remedied by correction of furnace temperature.

The proportions of various constituents of a steel have a great effect on the machining operations, a steel suitable for turning being unsuitable for broaching. The test will decide the best steel for any operations. Differentiation can also be made on a steel suitable for case-hardening and a steel which is not.

The non-ferrous alloys can be classified and controlled just as easily. For instance, annealed copper is very soft, which is sometimes a disadvantage for screwing. The addition of arsenic, silicon or zinc will give the required hardness, determinable only by the testing machine. For testing, the impression should be made where the strain set up does not weaken or damage the article, and the width of the impression should be less than the distance between its edge and the edge of the work.

Machines For Making the Test

This section is devoted to a description of the patent power operated hardness testing machine, the small ball hardness testing machine and the microscope for use with the latter. The power operated machine employs a 10 mm. ball with standard pressures of 3,000 and 500 kilograms. Its leading feature is that the time taken for the application, duration and removal of the load is uniform for all tests eliminating the possibility of errors due to the operator.

The machine consists of a weighing element and a straining element. The former is a system of levers by which the weight is transformed into a pressure on the work through the medium of the ball.

The straining element is intended for applying, maintaining and removing the pressure by means of a vertically moving cylindrical ram actuated by a cam, the latter being driven through a worm wheel and worm by spiral gears from a single pulley. Depression of a foot pedal gives one revolution to the cam which applies, maintains and removes the pressure. The small ball hardness testing machine is employed for more delicate work than can be dealt with on the larger machine.

Thin walled tubes such as cartridge cases and other hollow forms may be tested without internal support; cutlery blades, wire at successive stages of drawing, the cutting edges of tools and material even less than one-hundredth of an inch in thickness can be dealt with by this machine. This is accomplished by using balls of 1 and 2 m/m. diameter with loads up to 50 kilograms. A 5 m/m. ball is supplied for very soft material. Hardness numbers are calculated in the same way as for the ordinary Brinell test.

The machine is hand operated, the specimen being placed on a table, vertically adjustable on two threaded columns. By means of a hand wheel the specimen is brought into contact with the ball which is carried by a stirrup to which is attached the weights. The stirrup is again carried by an upper stirrup, which, upon being lowered by a handwheel, transfers the weight through the ball on to the work. A reverse movement of the handwheel raises the ball, and the impression may be measured by means of the microscope which is supplied at extra cost. A description of the microscope, together with operating instructions, completes this section.

Observations on the Ball Hardness Test

The theoretical derivation of the Brinell hardness number is discussed under this heading, and it will be found of great practical value in special cases where a combination of ball and load is employed for which tables are not available.

Brinell's first attempt at determining the hardness number corresponding to a given load and ball diameter, by dividing the load by the area of the circle made by the ball, was erroneous, as the hardness number was not constant if the load was varied. This, however, was partially overcome by dividing the load by the spherical area of the impression.

The result obtained, though only empirical, was accurate enough for all practical purposes, and is now the accepted method for determining Brinell hardness numbers. Where the diameter of the impression is determinable the formula used is—

$$H = \frac{L}{\frac{\pi D}{2}(D - \sqrt{D^2 - d^2})}$$

Where L = Load in kilograms.
D = Dia. of ball in m/m.
d = Dia. of impression in m/m.
H = Brinell hardness number.

If the depth of the impression is known,

$$H = \frac{L}{\pi D t}$$

t being the depth of impression.

A useful paragraph is included in this section showing the relationship which exists between hardness numbers obtained with different loads and balls of different diameters.

By employing loads proportioned to the square of the ball diameter the same Brinell number may be obtained with balls of different size, and this is illustrated by a short list giving various ball diameters with corresponding different loads, each combination of which will

give the same Brinell number. This information may be practically applied in obtaining the Brinell number for a special combination of ball and load which cannot be obtained from the tables. The rule is to divide the diameter of impression by the diameter of the ball and look out the Brinell hardness number in table 1 at the end of the book. Multiply this number by the load and divide by ten times the square of the ball diameter; this gives the required Brinell hardness number.

Some practical suggestions are offered for the actual carrying out of tests such as the diameter of impression desirable relative to the diameter of the ball employed; the depth of impression relative to the thickness of the work; the preparation of the surface to receive the impression in order to avoid surface hardening and to facilitate measuring the impression.

Brinell Hardness Number Tables

Six comprehensive and reliable hardness number tables, more than sufficient to cover all practical purposes, complete the booklet. Tables Nos. 1 to 4 are specially compiled for use with the small ball hardness testing machine, and cover combinations of ball and load of 1 m/m. and 10kgs., 1 m/m. and 30 kgs., 1 m/m. and 50 kgs., and 2 m/m. and 40 kgs. respectively. For the 5 m/m. ball, when used with a load of 50 kgs., Table No. 5 is provided.

Table 1 may be used for calculating the Brinell hardness number for any combination of ball and load. Tables 1 to 3 may also be used directly for a ball of 10 m/m. diameter with loads of 1,000, 3,000 and 5,000 kgs. respectively, by moving the decimal point in the diameter of impression one place to the right. Table No. 6 is a shorter table for use with a ball of 10 m/m. diameter and loads of 3,000 or 500 kgs.

From the foregoing it will be seen that the booklet is a useful acquisition —in fact, a practical necessity to all modern industrial concerns who are desirous of applying an efficient and reliable control over the heat treatment and machining of their products in the course of manufacture.

LATHE DIAL SCREW THREADS INDICATOR IN PRACTICE

(Continued from page 30)

3½, 4½, etc., threads per inch, the ratio of threads per inch in the screw to be cut to the threads per inch in the lead-screw are 1½ to 2, 2½ to 2, 3½ to 2, 4½ to 2, and so forth. These written in simple form are 3 to 4, 5 to 4, 7 to 4, 9 to 4, etc. Here the lead-screw makes four complete turns, while the screw to be cut is completing 3, 5, 7, or 9 revolutions, i. e., four revolutions of the lead-screw moves four divisions on the dial or a quarter-turn before register is obtained. When cutting fractional threads that include ½, therefore, the half-nuts may be engaged at every quarter revolution of the dial.

Next, we can consider the fractional threads which contain ¼, such as 1¼, 1¾, 2¼, 2¾, etc., threads per inch. In these cases the ratios of thread per inch in the screw to be cut to the threads per inch in the lead-screw are 1¼ to 2, 1¾ to 2, 2¼ to 2, 2¾ to 2, which written in simpler form, become 5 to 8, 7 to 8, 9 to 8, 11 to 8. In these examples the lead-screw makes 8 complete revolutions before register is obtained, the screw to be cut making 5, 7, 9 or 11 revolutions in the same time. Eight revolutions of the lead-screw move the dial eight divisions, which is equivalent to half a turn. Therefore where the fractional thread to be cut contains ¼, register is obtained and the half-nuts may be engaged at every half-revolution of the dial.

If the fractional thread contains ⅛, for example 1⅞, 2⅛, 2⅜, 2⅝, etc., threads per inch to be cut, proceed as before to find the ratios of the screws to be cut to the lead-screw. These are 1⅞ to 2, 2⅛ to 2, 2⅜ to 2, 2⅝ to 2, etc., which, simplified, are 15 to 16 17 to 16, 19 to 16, 21 to 16, etc. In this case, sixteen revolutions of the lead-screw are necessary before the half-nuts may be engaged, the work in the same time making respectively 15, 17, 19 or 21 revolutions. The dial also will have moved 16 graduations, i. e., one complete revolution, while the lead-screw has made sixteen turns. Thus if ⅛ occurs in the fractional thread to be cut, register is made and the half-nuts can be engaged every time the dial has made a complete revolution.

The half-nuts may be engaged as shown in the previous examples if the lathe has a four threads per inch lead-screw, a worm wheel with 32 teeth, and a dial with 16 graduations, as shown in Fig. 2. Before engaging the half-nuts when commencing to cut a screw, see that a graduation mark on the dial is opposite the arrow, or pointer, on the bracket. It is advisable also in cutting fractional threads to use the numbered divisions only, as these make it easier to reckon the half and quarter revolutions. Some turners prefer, when cutting fractional threads containing either ½, ¼ or ⅛, to engage the half-nuts only when No. 1 graduation comes opposite the pointer.

It must be understood that when the half-nuts are engaged, and a screw is being cut, the dial does not rotate, but as soon as the half-nuts are disengaged and the carriage stops, the dial then commences slowly to rotate. Fig. 3 shows a self-explanatory index plate which is supplied with the thread indicator. It is hardly necessary to point to the fact that such an appliance, properly handled can be of great assistance to the lathe operator in the production of work within fine limits of accuracy. Engineers cannot afford in these days to rely upon the old rule of thumb methods for the execution of good work, and advantage should be taken of any scientific appliance available.

COMPOSITION OF STEEL AND ITS MANUFACTURE

Steel is the name applied to carbonized iron, having a high tensile strength combined with elasticity. It was first made by the ancient Egyptians and other early races, by reducing very pure iron ore mixed with chopped wood, in clay crucibles, which were heated in charcoal fires blown by goat skin bellows. From this steel, the celebrated Indian sword blades were fashioned. No finer steel has ever been made. The term "steel" as used in early times, designated a form of carbonized iron which would harden or "temper" when dipped in cold water, after having been heated to a red heat. This definition no longer holds good, as the carbonized iron produced by modern methods and used extensively in structural work, goes by the name of steel. Up to the time of the invention of the open hearth process, the only commercial process of making steel was by decarbonizing cast-iron, and then recarbonizing the resulting wrought iron in the cementation furnace. Steel may now be defined as a metal produced by a complete fusion of iron or iron alloys, in a bath, the necessary properties being given after conversion by the addition of carbon or carbon alloys. Many theories have been advanced as to what steel really is. One held by many metallurgists is that "steel is an alloy of pure iron and carbon only," all other elements being regarded as impurities. Good steel is of a bluish, gray color, uniform in grain and having little lustre.

There are three distinct methods used in making steel, the Open Hearth, the Bessemer and the Crucible. The latter is the oldest of the present methods of manufacture, having been in use for centuries. The first two methods are probably the ones most commonly used at the present time. In these, the carbon in the cast-iron is burned out, while in the last method, the carbon is burned into the wrought iron. Other methods formerly used, were Cement or Blister steel and Shear steel. In commercial importance, the processes rank, Open Hearth, Bessemer and Crucible. It was not until the Open Hearth and Bessemer processes came into use that steel began to supplant wrought iron to any extent.

A WORLD POWER CONFERENCE

A world power conference, to be held in London in 1924, is now being organized by the British Electrical and Allied Manufacturers' Association, with D. N. Dunlop as director. The conference will concern itself with actual and potential sources of industrial power, and will, in particular, discuss the world's mineral fuel resources, hydro-electric power, irrigation and transportation, the improvement of technical education and other cognate subjects. It is anticipated that the conference will result in the compilation of mechanical progress and an improved means of exchanging information relating to scientific invention and discovery.

Practical Ideas From Practical Men

TOOL LAYOUT FOR ENGINE CYLINDERS

By Geo. Barrett

We often hear a discussion over the ability to purchase a certain piece of machinery cheaper than from a neighboring machine shop. The writer will describe the method used in manufacturing a gas engine cylinder, Fig. 1. In the first instance, I may state that the part described would take from 4 to 6 hours in any jobbing shop, the time depending on equipment and workmen's ability.

The set-up shown is used on a Libby turret lathe using specialized help and producing one cylinder every 35 minutes. The cylinder is first drilled for tapping hole A, Fig. 1, which is for 2½ in. drilled pipe, using a special centering fixture on a Baker Drill. This drilling operation is to assist the operator in setting the cylinder true in cradle chuck, Fig. 2. The method in setting job is by using first index of turret, Fig. 4, using centering bar A. This bar is made an easy fit to the drilled hole and a sliding fit to steel bush in spindle of lathe. This trues the back end of cylinder, the front end being trued by taper bush B.

The next step is to tighten set-screws A, Fig. 3, then pull over clamp A, Fig.2. locking by using swing bolt B, Fig. 3, after which the remaining set-screws are tightened, which leaves very little adjustment after removing centering bar.

The first step in machining is to face front of cylinder and flange, using tool C on cross slide, Fig. 4. This is to help rough boring tool D to keep its edge as we have already got under the hard surface of the casting. The boring tools are of the inserted type, using a rougher and finisher, being supported by a hardened steel bush in the lathe spindle and the pilot of boring bars.

The chamfering is done after finish bore with the tools E, Fig. 4, after which the flange is finished with cross-slide tool E. All tooling, and chucks are of a stout nature and when the cylinder is finished the bore is very smooth and true after setting on engine frame. The lathe used has also very good features in being substantial and speedy in the quick return and entering of boring bars.

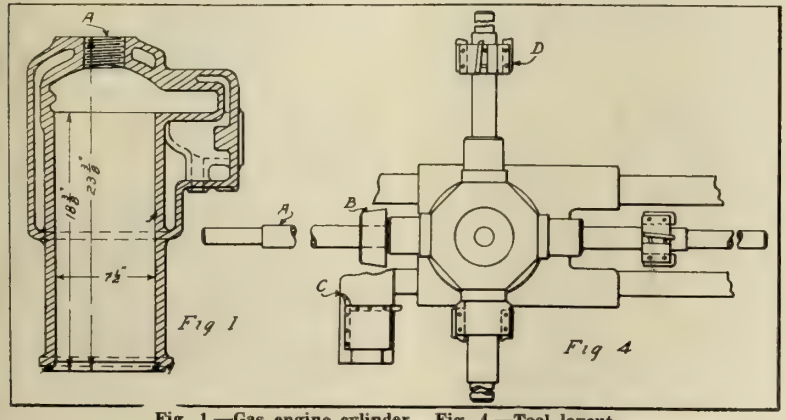

Fig. 1.—Gas engine cylinder. Fig. 4.—Tool layout.

INDUSTRIAL EFFICIENCY

By E. C. MacCormac

The late H. L. Gantt, one of the most capable and enlightened industrial engineers that America has produced, is reported to have said that the industrial efficiency of the United States was about 5 per cent. in 1919. This is a very remarkable statement coming from such an authoritative source, and has a number of very important implications. Let us study a few of these not necessarily in regard to the United States but in a general sense.

Capt. W. E. Elliott recently remarked that great difficulty was experienced by the British Ministry of Pensions in being able to tell a man what work he ought and ought not to do, and this physiological question was one upon which there was very little data available. It has been stated that owing to the faulty adjustment of the workers to the tasks which they are undertaking in industry, a sum of $300,000,000 per annum is lost in the United Kingdom, whilst another $350,000,000 per annum is lost through sickness. Whether or not this is right, there is no doubt that a very large sum is lost to industry due to these causes. With regard to the question of regularity of work, we still have to ascertain whether or not this is a good thing for the workers. Man has been brought up on spurts of energy and long rest periods, and that is why the soldiers during the war were happy as compared with the industrial worker to-day, who is subjected to long periods of hard, monotonous work.

Look at the present conditions in Russia where the Government has installed locomotive works at Sormorow, Kolumnad, and Brjansk, steel-plate works at Wykas, and wagon shops at Twer and Moscow. These works have promised to undertake a definite amount of work during a certain period. The Sormorow plant, for example, was entrusted with the production under six months, of eight new locomotives, heavy repairs to 30 locomotives, and the manufacture of a certain number of spare parts. The works, which employs some 8,500 workers, simply did the following:—new locomotives, none; locomotives repaired, 14; and about 80 per cent. of the number of spare parts promised.

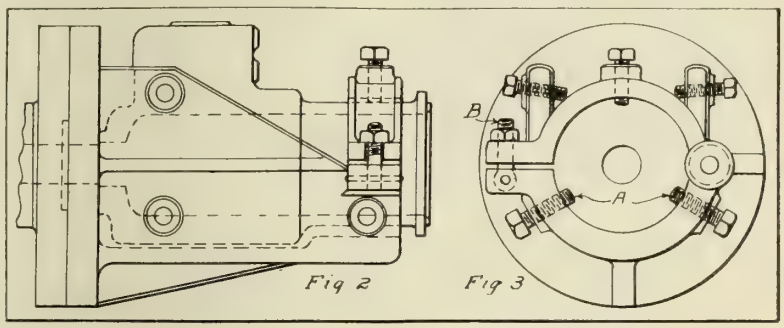

Fig. 2.—Cradle chuck. Fig. 3.—End view.

The reason for the present campaign against capitalism is clear when one begins to study its history. It got a bad name at the time of the introduction of machinery, and the consequent distress amongst the working classes following upon the discharge of many of the workers and the employment of unskilled labor at lower rates. It is true that distress at that time was acute, but the great improvements which had been discovered and which enabled goods to be produced at half the cost and half the trouble could not have been held back because they were going to hit a certain section of the community. The commun-

ity as a whole have benefited. Machinery was introduced when we were suffering from the effects of the Napoleonic wars, and steam had enabled us to recover ourselves. Then came the demand for better working conditions. It is unquestionably true that an industrial system, or even any particular industry, which fails to make possible adequate shelter, food, clothing and recreation for all of its operatives is unworthy to exist. Housing for those earning low wages or salaries should be legalized as a public utility; the manufacture of this class of homes as a profitable industry should cease and the Government, national and local, should at once adopt measures making possible the supply of this prime necessity of life."

Dr. E. M. Wilson's views on this subject are ably put, as follows:—

"Industrial experience has shewn that there is a far better thing than a minimum wage, namely, what one may call the 'optimum wage,' which means the best wage that can be paid to a man without crippling a business. The question of the best wage is a medical one. It means that a man must have enough to allow him to live in reasonably comfortable surroundings, to allow him reasonable pleasure, a reasonable amount of leisure, a reasonable amount to spend in emergency, and good food. Without that he could not keep up his efficiency and maintain his output."

REFERENCE DISCS AN AID TO MANUFACTURERS

By D. A. Hampson

Though gauges of the general "go, not go" type are considered the best form of measuring tool to use on manufacturing work, there are instances where the micrometer is preferred. The writer has a dozen machines—millers—running on work which has flat surfaces that we find are better measured with micrometers than gauges. The gauges would answer very well but the number that would be required would make the cost prohibitive and so, except in the case of half a dozen parts that are run steadily month after month, plain micrometers are used.

Now, the men on this work are semi-skilled and familar with the micrometer from long experience; as a consequence, we have no trouble from improper use or reading of the instrument. All our sizes but three are within the range of a one-inch micrometer and we bought several 1.000 in. reference discs with the first lot of instruments. Weekly, the micrometers are tested on these by a foreman and also tested at zero; these two tests may be made by the machine hands also at any time as one disc is kept with the machines.

Our sizes are such odd measurements as .687 in., .684 in., .758 in., 1.328 in., etc. Half a dozen basic sizes like this and then the rest made from these by a plus .083 in. and .125 in. With any instrument that is correct at the extremes of its range, it is still necessary to prove its correctness within its own graduations—and that is what we foun with the micrometers on our work. They would show wear at these points of greatest constant usage even though accurate at 0 and 1.000 in.

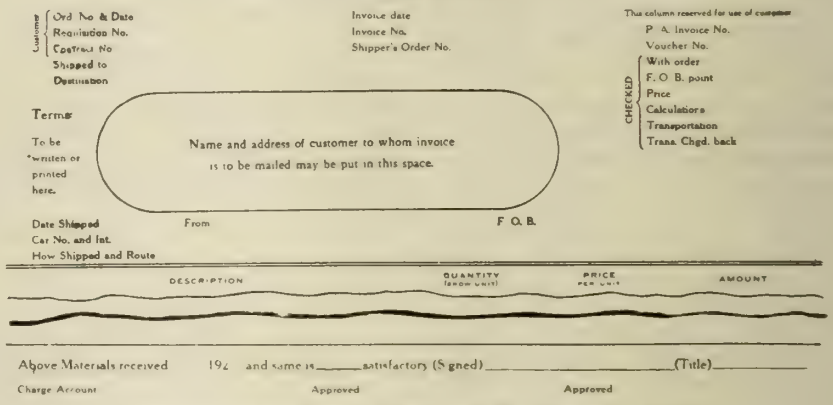
To remedy this troub.e, which was the cause of inaccurate work getting through, we had reference discs made for each of our basic sizes. These were Brown & Sharpe discs of similar form to those we already had. Now, when a thousand .758 pieces were to b run off, the micrometer to be used was tested on the .758 in. disc and corrected to it. For the over sizes, discs ground to these two thicknesses were secured and these used in conjunction with the basic sizes to form the test piece for the micrometer.

Manufacturers who are getting along without them will find reference discs or gauge blocks of unusual value to them. Too many places get along by trusting to the accuracy of an instrument within its own graduations or, worse, by using pieces of cold-drawn steel or chunks that have been planed up, the sizes of these latter being checked with Bill's micrometer which was the same as Joe Brown's who worked here in 1916 and "his micrometer was right."

NATIONAL STANDARD INVOICE FORM

Herewith is a sample of the seventh tentative form of the National Standard Invoice. This was developed at a conference of the four committees named on its face, the conference being held in Philadelphia, April 14th. During the summer the form will be put up to the conventions of the four associations for ratification. It embodies all of the practical suggestions which have been received from those using the present form during the year and a half it has been in force. These modifications, while not very great, eliminate the little difficulties which were met, and the form now is not apt to be changed for a number of years. The form which is now in use by a number of corporations was adopted by the National Association of Purchasing Agents at their convention in Chicago in 1920. It was afterwards endorsed by the National Association of Cost Accountants, as well as a number of railroads and other corporations. This form resulted from two public conferences, held a year apart in Philadelphia and Chicago, and the form represented what was then thought to be the most practical arrangement. Now that it has been in use for more than a year by a number of corporations certain constructive criticisms developed and were considered at the third public conference at Philadelphia, April 14, 1922. The seventh tentative form, adopted at the Philadelphia Conference, embodies all of the practical suggestions made. Because of this fact this form will undoubtedly meet with most enthusiastic support.

Seventh Tentative Standard Invoice Form
embodying constructive criticisms of present form received by
THE NATIONAL ASSOCIATION OF PURCHASING AGENTS
19 PARK PLACE, NEW YORK.



Form adopted by National Association of Purchasing Agents.

BRITISH HYDRO-ELECTRIC INVENTIONS

The countries richest in water power were naturally the first to develop hydro-electric enterprises and to design and construct the machinery for harnessing waterfalls in the service of man. Gt. Britain, which is far from well provided with water power resources, was for long absorbed in steam engineering, but latterly her engineers and manufacturers have thrown themselves vigorously and successfully into the hydro-electric field. One of the most recent signs of their activity is the production by a leading British firm, of several distinct improvements in hydro-electric machinery. One of them relates to the relief valve, which affords a safe means of escape for the water if at any time a turbine has to be suddenly put out of action. Most relief valves permit the water to escape in a solid jet, which is most destructive of anything upon which it impinges. By a most ingenious arrangement of valves the water is, in this new valve, given a whirling movement which opens out the jet to the form of a half-opened Japanese umbrella, thus rendering it quite harmless.

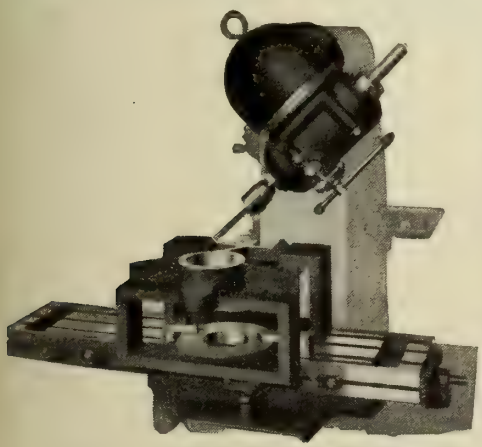
New Things in Shop Equipment

CYLINDER REBORING AND GRINDING MACHINE

A portable machine for reboring and grinding automotive cylinders has recently been offered to the trade. The machine can be used on open or closed cylinders up to a depth of 11½in. Many types of cylinders can be ground without removing the block from the chassis. A 1¼ h. p. motor is used to drive the machine, operating on 110 or 220-volt a. c. or d. c. current. The boring bar operates at a normal speed of 40 r. p. m. The bar is 2¾in. dia., with bearings 10½in. long. The grinding spindle is mounted inside the boring bar and runs on ball bearings at a speed of 5,000 r. p. m. The downward feed of the bar is automatic and is elevated by means of a crank at the top of the frame. The depth of feed is regulated by means of an adjustable automatic stop. The base of the machine can be clamped to the cylinder block and is so designed that it can be swung clear when desired. The device is located by dropping a conical plug into the top of the bore. The boring head is provided with three cutters, which are adjusted simultaneously by means of a central tapered plug. The head has a range from 2¾ to 3⅞in. After the boring head has passed through the cylinder, the device is merely swung on the base and the grinding head brought into working position. The grinding head is provided with an eccentric mechanism adjustable to a ½ in. throw. The entire device weighs only 140 lbs. and is easily handled by one man. These machines are made by the Simplicity Engine and Manufacturing Co., Fort Washington, Wis.

RING GAGE FOR SETTING REAMERS

A type of ring gage especially made for setting expansion reamers of the Critchley type has just been offered to the trade. These gages, known as "Simplex," provide for accurate setting of reamer size without the use of a micrometer, thus saving considerable time. The required size of gage is slipped over the reamer and the blades expanded to fit the ring; no other instrument or tool is necessary. It is advisable to hold shank of reamer in vise while adjustment is made. The rings are made of tempered steel and ground to size. Gages are made in standard sizes and can be furnished singly or in sets. All the reamers and bushings necessary for work on engine or transmission bearings are packed in one box, so that all parts are conveniently available. These sets are made by the Ampco Twist Drill and Tool Co., Detroit, Mich.



Milling attachment working at angle of 45 degrees.

THREADING DIAL FOR LATHES

A device, known as the "E-Z" threading dial, that may be attached to any engine lathe, has recently been marketed. The attachment consists of a cast iron bracket fitted with a brass sleeve in which is a smaller shaft carrying a dial on the upper end and a worm gear on the lower end that fits in the lead screw of the lathe. By the use of this attachment it is possible to cut almost any thread without using a cross belt to reverse the movement of the work, as the marks on the dial enable the half-nuts to be engaged at the proper time for each succeeding cut. The lathe may be run continuously and the use of this small device makes the ordinary engine lathe a more modern and economical tool. This device is being placed on the market by James M. Colven, Yonkers, N. Y.

MILLING MACHINE ATTACHMENT

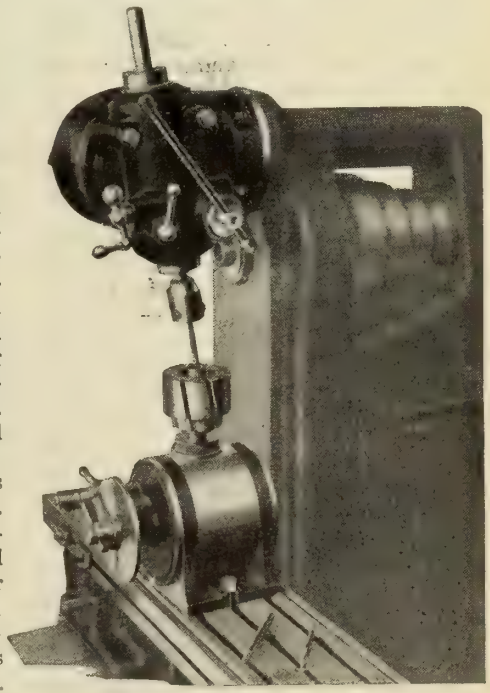
The milling and drilling attachment shown in the accompanying cuts has recently been placed on the market. The device is mounted on the face of the column immediately above the spindle and the drive is by means of a geared connection from the back end of the spindle through a sleeve substituted for the overarm. From this driving sleeve, motion is transmitted to the attachment through bevel gears. The method of locating and driving the device does not interfere with the free use of the main spindle. The two graduated swivel bases located at right angles to one another provide an unlimited range for operating, as every conceivable angle can be obtained. The spindle of the attachment is mounted in a graduated quill and can be moved in or out either by rack and pinion or by driving the pinion by worm gearing, providing the choice of two feeds in the ratio of 48 to 1. Sixteen spindle speeds are possible, ranging from 21 to 414 r. p. m. These attachments are manufactured by the Rockford Milling Machine Co., Rockford, Ill.

OILING ATTACHMENT FOR AIR DRILL

An oiling device that may be fitted to nearly all types of "Little Giant" pneumatic drills, has recently been developed. Its purpose is to provide a better means of lubrication, reduce the possibility of leakage and the frequency of oiling, and the saving of time and labor. The device consists of a sliding plunger that closes the passage of oil from the drill when the machine is operating in any position. Other improvements made in these drills is the interchangeable feature of the toggles and connecting rod units. The connecting rod is fitted to the piston by means of a ball and socket joint. Hinge-split collars are used which provide a large opening through which the crank pin bearings are lubricated. The new design makes it possible to assemble or disassemble any of the connecting rod units without dismantling the entire drill mechanism. These improvements have been developed by the Chicago Pneumatic Tool Co., of New York.

EXPANSION REAMER

A new type of inserted-blade expansion reamer has recently been offered to the trade. The blades are adjustable along slots cut in the body of the tool, the face of the slot being at a slight an gle to the axis of the reamer. The shanks are made of alloy steel while



Attachment working on cutter head.

the blades are of semi-high-speed tool steel. A double relief is given to each blade, a narrow land immediately back of the cutting edge and additional relief near the back of the blade to prevent dragging on the finished surface of the bore. The blades are supported on either end by means of steady rings, slotted on one side to receive the end of blade. By means of long threads and nuts these rings and the blades are adjusted along the slots to the desired position for size. It is usual to adjust the reamer to take light cuts, so that more accurate work, and smoother finish is obtained. These tools are made in seventeen sizes ranging in size from 15-32 in. to 4-1/16 in. dia., the blades of the latter being 7¾ in. long. These reamers are made by Samuel Hocking & Son, Lancaster, Pa.

SLITTING SHEAR AND BAR-CUTTER

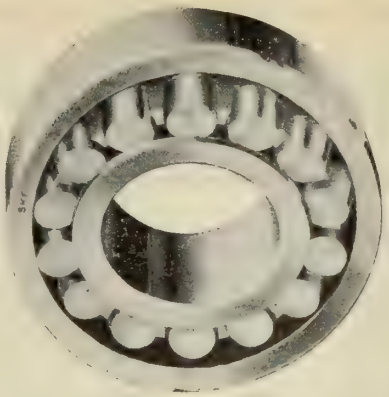
A machine especially designed for slitting steel sheets and cutting bars, and intended for use in iron shops and warehouses, has recently been placed on the market. The shear knives are 10 in. long and are capable of cutting plates of ½ in. thickness, or flat bars 6 in. x ⅝ in., at a speed of 30 strokes per minute. Five-piece knives are used in the bar-cutter, and will cut a wide range of structural shapes and sizes; 4 x 4 x ⅜ in. angles, 3 x 3 x ⅜ tees, 1⅝ in. round or 1½ in. square bars. Special knives may be fitted to accommodate other shapes. The frame is of "armor-plate" construction. Drive shaft bearings are bronze-lined and fitted with oiling rings. Gears are of semi-steel. The machine requires a floor space of 5 ft. 4 in. by 2 ft. 8 in., and weighs about 4,500 lbs. This shear is made by The Buffalo Forge Co., Buffalo, N. Y.

HEAVY DUTY ROLLER BEARING

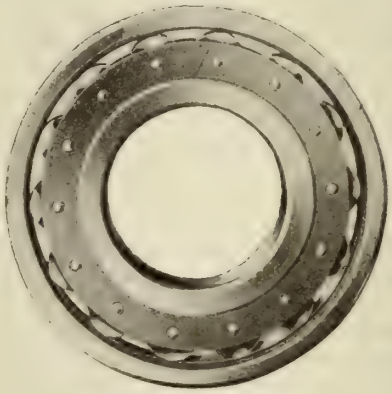
The S. K. F. Ball Bearing Co., King St., W., Toronto, have placed on the market a new self-aligning roller bearing of very rugged construction. The design allows for a double row of rollers, these being located in strong two-piece cages or retainers which compensate for creep in any one set of rollers when heavy thrust conditions are encountered. This feature prevents binding or skewing of rollers as far as is practically possible. The general construction follows the line of S. K. F. self-aligning double-row ball bearings.

This company have also introduced a new cylindrical or short roller radial bearing built on the same principle but without the self-aligning feature. Both lines are interchangeable in dimensions with the present standard ball bearings, and the cost is approximately the same. These two features can readily be appreciated by those in charge of a plant.

The two illustrations give a general idea of both styles of bearings, and they have been designed for special heavy service such as on railways, street cars, and any heavy machinery



Self-aligning roller bearing.



Short roller radial bearing.

where shock loads and comparatively low speeds are encountered.

For example: they have been in use on two trains on the Pennsylvania Railroad, one between Philadelphia and Pittsburgh, known as the Pittsburgh express, the other between New York and Pittsburgh, known as the Quaker City express. These bearings were installed the early part of last December and have been in steady service ever since, running at the average speed of 40 to 45 miles per hour. According to actual tests, they have shown a saving of 15 per cent. on coal, a large saving on oil consumption, and a marked drop in the heating of journal boxes. At a later date we intend showing more details of construction and application of both types of bearings.

COMBINED COLLET AND STEP CHUCK

A combination step and collet chuck, for use on machines with hollow spindles, has recently been placed on the market. As no draw bar is necessary these chucks have the advantage of handling larger stock than usual. The body of the chuck is fastened to a face plate that is secured to the nose of the spindle. The annular bevel gear within the chuck is mounted on ball-bearings, and threaded internally to fit the threaded end of the collets. A pinion wrench is used to turn the annular gear, it being inserted through a hole in the body of the chuck. Internal collets are furnished to hold all commercial sizes of round stock up to one inch diameter. Special provision is made for handling work of larger diameter by means of step rings. By using the larger rings and corresponding step collets, work up to 8 in. dia. can be held. These chucks are made by the Hartford Special Machinery Co., Hartford, Conn.

COMPARATOR ATTACHMENT

An attachment especially adapted for the Harkness comparator has recently been placed on the market. In order to permit the operator of the projecting lantern to have the projected and magnified image shown on the screen within his reach, a mirror is employed at some distance from the lantern so as to throw the image on the back of a ground-glass screen. The mirror used with this attachment is especially constructed with a deposit of silver on its front surface. This provides the highest degree of reflection and gives great accuracy so that a magnification of 1/100 diameter can be detected. Owing to the fact that most gears are chamfered on the end of the teeth, the instrument is focused at some point along the face of the tooth rather than on the very end of it. A slight tilt is given to the gear so that the light rays strike on the side of the tooth. When a needle is placed in the plane to be explored, it gives a very sharp projected point and shows the outline of the tooth clearly. The outline lies in the image on the screen between the point of the needle itself and the reflection of it in the face of the tooth. No polishing of the tooth face is necesssary. This attachment is being manufactured by the Jones and Lamson Machine Co., Springfield, Vt.

IMPROVED WATER TUBE BOILER

In Great Britain the water tube boiler for both land and marine purposes has been brought to a high state of perfection, but still, in the hands of British inventors, improvements are continually registered. One of the latest novelties in this line is a boiler specially designed to overcome one of the incidental difficulties sometimes encountered with earlier types. The lowest tubes in the boiler are those in immediate contact with the hottest flames, and therefore most liable to be burnt out if there is not a rapid flow of water through them. This burning out does not take place unless the boilers are being driven very hard—as they would be in the case of a sudden demand for steam. In the new type the lowest rows of tubes are provided with a separate supply of water in order to give the vigorous circulation required for safe working on emergency. Two types of boilers have been designed, one adapted for cases where the water supply is very pure and the other for installations where comparatively hard water is used. In the latter case the tubes are straight so that they may be very rapidly cleaned.

Stupendous Wage Losses

THERE ARE those who claim that strikes now going on in the coal mining, railway and other industries, are foredoomed to the failure that has marked the settlement of so many of these struggles in recent years. Whether such prediction is verified remains to be seen, but it does appear that the actual loss in wages has been a most serious item as against the consideration involved. At the wage proposed, railway shopmen would receive 80 per cent. higher wages than in the pre-war period and somewhat more than mechanics are being paid elsewhere, and this at a period when industry is trying to struggle back to normal.

It is estimated that American workingmen are losing five million dollars daily in wages, irrespective of the loss to other mechanics whose employment is impaired by the strikes. There are one million and a quarter men out, and of these 80,000 are textile workers; 155,000 anthracite coal men; 573,000 bituminous miners, and 400,000 railway shopmen. An authority estimates that on an eight hour day basis the loss is equal to ten million man-hours per day.

These are stupendous figures, but one thing taught by the world war was the ability to cope with or ignore exceptional factors according as they affected general welfare. The American workingman would appear to have adopted the mass formation as a means of demonstrating his potentiality.

Struggling With Strike Problems

OUT OF THE mass of daily newspaper conversation about the coal and railway shopmen's strikes, the fact appears to develop that, should the trouble be protracted, some attempt will have been made to secure adequate supplies of coal for domestic and industrial purposes. Processes, however, are laborious and action beset with devious problems. Many people are asking why this, that or something else has not been done, and, if so, how or where, and the situation has the earmarks of an absolutely new proposition.

Out of it all comes some useful information. Manufacturers are working together, and it is hoped that sources of supply in Nova Scotia, Wales and even the United States may not prove altogether unfruitful. Before the end of the present year, Ontario will require about ten million tons bituminous and two million tons anthracite, and Quebec two and one-half million tons bituminous and one million tons anthracite. Under normal conditions, Canada consumes between 30 and 35 million tons of coal, of which 18 to 21 million tons are imported from the United States and the balance is from Canadian mines. Nova Scotia, Alberta and British Columbia produced some five million tons last year in addition to what they used. That is the Canadian end of the situation.

Some criticism is expressed with regard to the tardiness, in official circles, toward making definite survey of the country's requirements and sources of supply by means of special representative, as during the war period. The question is also asked why the possibilities of Nova Scotia mines were not appraised in preference to those overseas, but some consideration is probably given the fact that these mines are not altogether free from strike menace, although going strong at present. With regard to Welsh coal, it is pointed out that time is here the big element, and it is felt in some quarters that but a limited relief may now be expected from that quarter. A ray of hope appears occasionally, such as the statement of an American dealer to the effect that he has contracts for 100,000 tons for Ontario, and that he believes the strike will be over in two weeks.

In the meantime, an attempt to get the railway men back to work in United States is being made by President Harding. Railway executives, however willing to abide by the decisions of the Railroad Labor Board, declare that they will not reinstate strikers with unimpaired seniority rights. On the other hand Samuel Gompers, president of the American Federation of Labor, hints at a general strike to aid striking miners and shopmen. Against this is the report that drastic federal control, supervision and regulation of the coal industry, to avoid future strikes, is now in contemplation and it is generally agreed that this industry, above all else, is the one most in need of such control.

So it goes. Experience supplies the consolation that a situation may be entirely out of hand to-day and to-morrow may be under perfect control. The problem calls either for a man or a miracle to develop an organization that will safeguard the interests of the country generally.

Picking Off An Opportunity

IT WAS pointed out in these columns recently that exceptional business opportunities existed in Canadian mining regions for manufacturers of heavy machinery necessary in the handling and treatment of products from that source. Now comes the interesting announcement that a large manufacturing concern in the East is about to convert its plant to this purpose, as offering a more continuously active field than that in which it was engaged, that of shipbuilding Canadian rights have been secured upon British and American equipment such as conical mills, lime and cement kilns, trucks, cages, rotary dryers, skips, washing and crushing equipment, and as a result much work will be retained for Canadian industry.

Transportation Difficulties Cause of Higher Prices

Rail and Coal Strikes Result in Scarcity of Materials—Deliveries Are Uncertain—More Furnaces Closed—Steel Production Now Slowing Up—Pig Iron Still Advancing.

CANADIAN markets are beginning to reflect some of the strike difficulties that are affecting business on the other side. Iron and steel deliveries are becoming more and more problematical and positive scarcity is developing in certain bar and sheet sizes. Prices are trending upward and for new orders carrying specific are meeting with a more or less indifferent reception in some quarters. It is said of one mill that it could draw steel from now until the middle of October on present orders alone.

The situation is therefore becoming an increasingly difficult one for the buyer. One development will undoubtedly be the elimination for the present at least, of price-cutting that made its appearance in certain lines. While materials are difficult to obtain, and increasingly scarce, a tightening tendency is sure to manifest itself.

Strike conditions in the States have created an acute situation in the steel and iron industries and additional blast furnaces have been banked due to the scarcity of coke. It appears that consumers are fairly well stocked with steel. The production during the past several months has shown no marked falling off, in fact increase is reported for some months, so that with consumption light the sales of the past period must be largely for consumers' stock or dealers' and makers' warehouses. The duration of strike conditions, however, is having its effect on industrial activity as a slowing-up process is now in progress.

Toronto

August 9

SCARCITY of materials, caused by coal and rail strikes, promises to be responsible for a decidedly upward swing in iron and steel prices within the next three weeks. The demand in all lines remains fairly active and for prospective work there is likely to be a movement toward having requirements booked before any drastic change occurs. Already, big steel producers who have attempted to keep prices beyond criticism announced an advance of $3 a ton on all lines—shapes, bars, and plates—but deliveries are somewhat problematical. Considering the circumstances, it is remarkable that a Toronto firm reports the arrival of three carloads of hoop materials which left the Pittsburgh district only five days ago. This is considered exceptional service, and bears out the information published some days ago in these columns that conditions were somewhat better in and around that particular district than in any other. Canadian prices also show the upward tendency. The sheet and bar markets are decidedly firm, and although no definite announcement has been made as to advances beyond present levels, such a development, it is claimed, is not to be long delayed. Steel bars are in particularly strong demand and specific dates on new business are a somewhat difficult if not impossible proposition. Mills are said to have good supplies of billets and blooms, and present bookings are likely to run into October.

The pig iron situation also displays evidences of uneasiness. Although a two-dollar advance was recorded two weeks ago, it is now predicted that the upward swing has not yet reached the limit, and $35 pig iron is said to be within the range of early development. This would bring the market up to the level of May, 1921, but none will venture the absurdity that the fancy prices of two years ago, something over $50 a ton, will be repeated. It seems good advice to buyers that present market trend is entitled to immediate consideration.

Iron and steel bars and sheets reflect probably more than any other department the tightening tendency of the market. There is a marked scarcity and buyers are finding it increasingly difficult to meet requirements. Price advances are predicted. Current quotations follow:

Iron bars	3 15 to 3 25
Steel bars	3 15 to 3 25
Reinforcing bars	3 15 to 3 25
Steel hoops	4 25
Tire steel	3 15
Spring steel	7 00
Band steel, No. 10 gauge and 3-16 in base	3 65 to 3 75
Small shapes	3 25
Sheets, black, No. 28	5 25
Sheets, blue ann., No. 10	4 25
Canada plates, dull, 52 sheets	5 25 5 25
Canada plates, all bright	6 00
Galvanized Sheets. No. 28	6 35

Scrap metal markets are about as inactive as they could possibly be. "It is largely a problematical proposition," said an authority. "You may attribute it to the coal strike as much as anything. Consumers are awaiting some definite action looking to the end of the present trouble. There is nothing doing and the price situation remains the same." Quotations are:

Copper, light per 100 lbs.	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper Wire	11 00
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	4 85
Light brass	3 50
Medium brass	4 50
Scrap zinc	4 00
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	11 00
Axles (wrought iron)	16 00
Rails (scrap)	11 00
Malleable	11 00
No. 1 machine cast iron	16 00
Pipe, wrought	6 00
Car wheel	16 00
Steel axles	15 00

Non-ferrous metal markets show little change. Prices are firm but the demand is featureless and indicative of none of the unsettling influences in steel and iron. The New York market is reported as quite active while foundries were buying against actual requirements, but some reluctance to accumulate supplies was in evidence. Brass mills and wire drawers are reported to be taking large tonnages of copper. There was a slight advance in casting copper, and zinc went up 25 cents on activity among brass and zinc mills, and sheet galvanizers. London tin markets are reported as active and some slight advances were recorded. Current quotations are:

Lake copper	17 25
Electrolytic copper	17 25
Castings, copper	17 00
Tin	36 25
Spelter	7 50
Lead	7 00
Antimony	7 40
Aluminum	21 00

Owing to the drop from $3.25 to $3.00 a barrel in crude oil, some reductions are reported in the general oil list this week. Gasoline is down a cent and a half and royalite and polarine oils are lower by one cent.

There is a strong market for butt and lapweld pipe, but present prices hold. Skelp and other materials are increasingly difficult to obtain, largely as the result of shipping problems.

In machine tools and supplies the outlook, at least, is encouraging, although in the supply department, business is reported to be quite encouraging. July was a better month than it was last year, and half-yearly reports show, in some cases, a marked improvement over the same period in 1921. Reviews of general conditions are such as to cause optimism as to the autumn season, and while nothing great is anticipated, the feeling is that aggressive work will have far better results.

Montreal

August 9

DESPITE the general stiffening of price in different commodities there is little evidence of increased sales in any particular line. The prevailing tendency among iron and steel men seems to express a waiting attitude, as early future action is dependent on the trend of events in the coal and rail situation in the States. Dealers here are awaiting the outcome of present negotiations with a great deal of interest. An indication of American conditions, which rules the market here, is the fact that of the twenty-two furnaces in Buffalo, only

one is offering to-day and that at $30 as against $20 a short time ago.

Iron bars	3 15 to 3 25
Steel bars	3 15 to 3 25
Reinforcing bars	3 15 to 3 25
Steel hoops	4 00
Tire steel	3 15 to 3 25
Spring steel	6 00
Band steel, No. 10 gauge and 3-16" base	3 25
Small shapes	3 00

The market in pig iron is virtually unchanged, although prices on some grades show an advance of $3 a ton.

Non-Ferrous Metals.—Movement in this market continues light with prices firming. The situation as regards prompt shipment may develop an advance on some metals due to the evident scarcity. With prospect of higher quotations the week's prices are firm as follows:

Lake Copper	17 75
Electrolytic Copper	17 50
Castings, Copper	17 25
Tin	36 25
Lead	7 00
Spelter	8 25
Antimony	6 50
Aluminum	22 00

Machine Tools and Supplies.—The activity in machine tool equipment is still confined to an occasional sale of used machinery with little inquiry for new tools. The movement of supplies continues to be an encouraging factor in an otherwise dull situation. The purchasing, however, is still for immediate requirements and few manufacturing plants are buying heavily for future needs. While this state of mind continues, business will be more or less of the forced variety, but when industrial activity takes an upward turn, the depleted condition of a large number of plants will ultimately mean a heavy demand for all classes of equipment.

Scrap Metal.—Little of interest has transpired in the old material market and the movement of scrap is still light. Local prices are firm at following quotations:

Copper, light, per 100 lbs.	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper Wire	11 00
No. 1 compositon	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 00
Light brass	4 00
Medium brass	5 50
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton.	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	20 00
Pipe, wrought	7 00

Pittsburg

August 9

PRODUCTION of pig iron in July, was at a rate only 1.6 per cent. under the rate in June. As noted in recent reports, many blast furnaces were compelled to bank or blow out in the last two or three weeks of July owing to coke shortage, due to lighter receipts of coal at by-product coking plants, resulting chiefly from the railroad shopmen's strike of July 1. This would have suggested a very considerable decrease in pig iron production in July. The decrease in the rate of production did occur, but quite a number of furnaces had blown in during the latter part of June, adding little to that month's output. Transportation conditions are improving, as the railroads make headway in overcoming the effects of the strike, which is not settled formally. The coal strike continues. Thus the prospect is that pig iron production in August w be materially below that of July.

The slight drop in pig iron production from June to July was almost entirely among merchant furnaces, the steel interests having a good output, and as the steel works may have used a somewhat larger proportion of scrap in July it is possible that their production of steel ingots increased a trifle. At any rate it cannot have decreased materially. The ingot report for July will be out in a few days.

The important point in this matter of steel production is that a fourth month has been added to the list of months in the coal strike in which there has been heavy production and this means a great deal of steel shipped. April saw a heavier production of steel than any preceding month since November, 1920, May showed a material increase over April, and June a slight increase over May, while July at any rate did not go back to any extent. The result is that steel production in the four months after April 1, when the coal strike started, has been 40 per cent. greater than in the four months preceding April 1. The average rate of production in the past four months has been about 36,000,000 tons of ingots a year. This is only 14 per cent. under the rate in the first nine months of 1920, when steel was regarded as being in exceptionally heavy demand.

Consumers Well Stocked

In the circumstances, there is a possibility that some consumers are pretty well stocked with steel. In February, March and April the common view was that a considerable part of the steel buying at that time was in anticipation of curtailment in steel production arising out of the coal strike. It must be remembered that the coal strike was universally expected and not a few people thought it likely to prove the greatest strike in the history of the industry. While there may have been little stocking of steel in a speculative way, it was the testimony of steel producers that customers were taking in steel against contracts they held and would be executing in the later months of the year, contracts for making manufactured steel products and contracts for construction work.

The reduction in steel production that has been occurring, and the further reduction that is practically certain prospect for the next few weeks, therefore, does not necessarily promise that there will be a shortage of steel. The present dullness of the market is in keeping with this analysis. There is some urgent demand for prompt shipment, with delivery premiums naturally being paid, but the tonnage involved is not large. For delivery late in the year hardly any business is being done. The mills insist that they would not sell in any event, but the case does not come up to any extent, as buyers are not inquiring.

Instructions to Curtail

It is stated on excellent authority that some buyers of steel have instructed mills to curtail shipments. This may not involve much tonnage, but it is a significant development. Whether the buyers in question have accumulated extra stock, or are having their operations curtailed by coal shortage, cannot be learned precisely. There may be a combination of both circumstances.

Unless transportation and coal conditions improve sharply in the very near future, there will necessarily be some curtailment in steel consumption, for it is generally held that there is now a real shortage of coal. It is even possible that coal shortage may affect consumption of steel more than production, for at the present time the iron and steel industry is running partly on its stocks of coal.

Reports, rumors and guesses as to an early ending of the coal strike have been thick, but are not worth analyzing. It is a common remark in trade circles that when the strike is settled it will require several weeks to restore normal production and distribution.

Prices of steel products for forward deliveries, practically "delivery at mill convenience" are unchanged. They are partly nominal, representing in some cases simply levels at which mills would sell if they cared to sell at all. When, however, a buyer has a definite construction job on hand, involving work that is certain to be done, he can generally buy the steel or get a reservation.

Bars, shapes and plates remain at basis price of 1.70c., while early deliveries command somewhat greater premiums than two or three weeks ago, sales being reported up to about 2.00c. in some instances.

Sheets Quiet

The sheet market is quiet in point of turnover. Mills adhering to basis prices, at 3.15c. for common black, are sold up as far as they care to go, as a rule, and most of the buying, such as it is, is at premiums of $2 to $5 a ton, for early shipment.

The June report of the National Association of Sheet & Tin Plate Manufacturers, representing about two-thirds of the sheet industry, shows unfilled tonnage July 1, equal to 1.8 months of production at capacity, with stock sold but unshipped of about .3 month, so that the orders would require operation at capacity for 1.5 months or

(Continued on page 46)

Country Approaches Period of Better Business

Unmistakable Signs of Returning Prosperity—Business Man Makes Survey of Western Ontario Cities—Finds Industry Well Employed—Massey-Harris Announce Policy of Production—Better Market for Implements.

RETURNING from a review of a considerable portion of western Ontario, a representative of large machinery house reports that present activity and the future industrial outlook warrants a genuine feeling of optimism Such cities as Guelph, Kitchener, London, Windsor and those of the Niagara peninsula were visited, and it was found that industries, in the majority of cases, were well employed. Particularly does this apply to those associated in any way with motor car enterprises, or with building and engineering operations. The market for machine tools remains quiet, but the opinion is expressed that inactivity cannot long be protracted in this deparoment. Improvement in general conditions must soon exert a beneficial influence.

"When I say that we are just turning the corner, I do not mean that we may expect a lot of business from large concerns with heavy overhead," said the representative referred to. "It is my opinion that the small manufacturer is going to be responsible for a nice volume of business. He is the man who can adjust his equipment to meet almost any requirement. His plant is not laid out for specializing and as a result, he is going to get business that the larger man, the specialist, does not care to handle. What he wants is business in his own line, and in a great many cases he is getting it.

Better Buying Feeling

"There has been a feeling among buyers that anything suggestive of expenditure was almost repulsive. It was a period of extreme conservatism. I think that feeling is disappearing and while we must not expect too much, the general tone is decidedly better. It only requirees a trip out through such cities as I have named, to convince one's self that quite a lot of work is going on. Some of it is of a public character, such as the Welland canal, but on the other hand, many factories are busy and those who are not are becoming exceptional.

"This does not mean that the time has arrived when business will walk into your office and plead for immediate attention. That time, I think, has gone forever. One of our best men adopts the plan of getting in touch, if possible, with the man who actually knows the immediate requirements of a shop. Thus, in calling upon a plant recently he was advised that nothing was required. In walking through, he noticed that an emery wheel was worn almost to the flanges. He called the attention of the boss to this fact and it transpired that they were facing a shortage on wheels, and further observation revealed a similar condition as to hacksaws. These are trifling things, but they serve to demonstrate that an aggressive, though tactful, policy has merit under present circumstances. One good feature of the times through which we are passing, is that it has taught us all—the big manufacturers, the small shop and the dealer, all alike—that it is necessary to hustle if we are to get anywhere. Having developed that habit once more, and there was a time when it was almost forgotten, we will, at least, be more deserving of better things."

Ford May Build Foundry

Reports from the Windsor district have some outstanding features. One is to the effect that the Ford Company are proceeding with a structure 400 ft. wide and 1,300 ft. long. In this they will house their machine shop, and, it is also understood, will manufacture their own bodies. It is further intimated that they will build and equip a large grey iron foundry. This may not be good news to many plants who are serving the Ford Company in this respect, but it is in line with the Ford policy to have their every department as selfcontained as possible as a necessity in dealing with growing competition.

While the Dodge people have not yet started building operations, it is a fact that they have bought 7½ acres of land in Windsor with the evident intention of establishing a Canadian industry thereon.

The Canadian Salt Company, Windsor, is also making extensive alterations to plant.

Improved activity is reported from boiler manufacturers. One Toronto plant is working night and day on boiler and tank business and in addition is turning out some heavy equipment used in the manufacture of motor car tires.

Massey-Harris to Speed Up

One of the most important announcements of the week is made by Thomas Bradshaw, general manager of the Massey-Harris Company, Toronto, that a more active production schedule had been decided upon for autumn and winter months. The annual inventory-taking period in this industry begins Aug. 15, and lasts for two weeks. Confidence in the future is behind the company's plans, which will mean the employment of about 1,600 men in the Toronto plant and 900 in that at Brantford. The program of increased activity indicates that normal conditions are felt to be approaching and that the organization prepared for good times will naturally be the first to participate in them.

The farmer, especially in Eastern Canada, is buying more implements, while in the West, because of piled-up indebtedness that has to be liquidated, the farmer is more conservative. Sales volumes are up to those of last year, however, and taking price reductions averaging 25 per cent. into consideration, this means that more implements have been sold. Stocks of both finished products and raw materials have been reduced to a low point. Consistent with the trend of business, and now that better conditions are in sight, activity will be all the more pronounced. It is understood that production in these plants will be close to 80 per cent. capacity. This in itself is one of the most cheering developments in the industrial field and is significant of better things.

Crop reports from the West continue to be encouraging, and manufacturers report that an improved buying impulse is evident. Farm supplies of all kinds are feeling the benefit of the movement which has behind it that inevitable stimulant contained in the prospect of a good yield.

All reports therfore point to better feeling and greater confidence in the future. While experience advises against great expectations, the signs are unmistakably in favor of reasonable optimism.

Guelph is Busy

"The industrial situation is very favorable at the present time," writes H. Westobey, secretary, Guelph Chamber of Commerce.

"The textile and rubber people are very busy, and the iron and steel industries continue to show a steady improvement. There is practically no unemployment in the city, although with the closing down of much of the out-of-door work, which is being carried on by the civic authorities, such as street paving, renewing the radial railway line, and such like works, there may be a certain amount of unemployment in the city during the forthcoming winter. A great deal depends, of course, on the settlement of the coal strike on the other side. This has not yet had much effect on our industrial establishments, but undoubtedly it will have a great effect if unduly prolonged. The situation to-day is much more favorable than it was a year ago and our manufacturers all appear to entertain a very hopeful view of the future."

Oshawa Reports Great Activity

Industrial conditions in Oshawa during the past month have shown great ac-

News From the Industrial Field

Customs collections for Galt, Ont., for July show about 50 per cent. increase over the same month last year. The amount is $90,084.13.

Lewis Staples, Bethany, Ont., has lost two shingle mills by fire in the past thirteen months. One destroyed a few days ago had just been rebuilt.

Fire Losses for Kitchener, Ont., for the first six months of the year were $16,967, a reduction of about $3,000 for the same period last year.

The Canadian Salt Co., Windsor, are installing a 150-ton Canadian Fairbanks Morse truck scale. They are also making extensive changes to their plant.

New Car Barns for Kitchener, Ont., will be opened shortly. They will have three times the capacity of the present barns. The dimensions are 120 x 160 feet and will house 25 cars.

In accordance with the variation in the cost of living, statistics for the last quarter show that the basic wage in the Australian Commonwealth has increased from 78 shillings per week to 81 shillings 5 pence.

A gasoline tank of the British American Oil Company plant, Toronto, exploded recently, killing a workman. It is thought that gas fumes, accumulating in the tank, caused the explosion. The loss is estimated at $6,000.

In order to meet the threatened coal shortage, Toronto Board of Control has placed orders for $100,000 worth of Welsh coal for immediate shipment. The Board will ask the city council to vote another $500,000 for coal purposes.

Windsor, Ont., has a population of more than 41,000, an increase of 4,000 in the past year. The eastern part of the city has made great strides in building. The present year will probably show a record in that respect.

Almost Every Merchant flag in the world is seen among the shipping in the harbor of Sydney, N.S., clamoring for coal. Sydney piers are working 24 hours a day, and double shifts have been put on the steam shovels at Glace Bay coal banks.

Toronto is negotiating for the purchase of the Dominion Shipbuilding Co.'s plant in that city, which at the time of recent assignment was valued at $523,634. The plant may be occupied by the Dominion Envelope and Carton Co., employing over 1,000 hands.

That Sections of the Canadian National Railway between Toronto and Port Hope may be electrified shortly was the statement made to deputations recently by Premier Drury. He stated that he has already taken up the project with the Federal Minister of Railways.

Extensions Have Been made to three industrial plants in Woodstock recently and 30 new residences built. Forty permits were issued in the past month, amounting to $21,426, as compared with $7,258 for July last year. The total for the city so far this year is $117,202, as compared with $75,634.

A railway amalgamation, under a total capital of £348,000,000 is announced from London. The reorganization includes the Great Central Railway, Great Eastern Railway, Great Northern Railway, Great North Scot and Railway, North British Railway, North Eastern Railway and twenty-six small companies.

The Mountain Lumber Manufacturers' Association of British Columbia, announces a reduction of fifty cents per thousand feet in the delivered prices of all principal grades of lumber in order that the benefit derived from lower lumber freight rates to prairie points may be passed on to buyers and consumers of lumber.

Working night and day in their boiler department, the plant of the John Inglis Co., Toronto, is the scene of great activity. With the exception of a number of vulcanizing cylinders for the Goodyear Tire Co., and some extensive replacement work on a 500-ton blast furnace, they report that the demand is quite general and applies largely to their Kawanee type of heating boiler. Quite an amount of tank work is also being done.

Sydney, N. S.—A second blast furnace may be blown in at the Sydney plant of the British Empire Steel Corporation in the near future, if general labor and business conditions permit, it is stated here officially. The second furnace will make pig iron for foundry purposes, a branch of the market which has shown much improvement lately. It is also reported that a battery of ninety coke ovens will also be put into operation.

Amherst, N. S.—Work on the car-wheel order at the Canada Car plant is proceeding. It is expected that when work is fully under way the number of men will be increased to thirty. The order from the C.N.R., as stated before, is for 2500 wheels and to this there has been added another small order from the C.P.R. at Kentville for 100 more. These are for use on the Dominion Atlantic road. It is hoped that before these contracts are completed there will be many more of the same kind.

The Johns-Pratt Co., Hartford, Conn., whose selling arrangements through Johns-Manville Inc., were recently dissolved by mutual consent, have established a Boston office at 161 Summer Street, which is in charge of Daniel Fitts and Harold E. Morse. It is intended to have complete representation at this office for the following products of the company—Noark fuses and meter protective devices, also the Johns-Pratt moulded products.

By the Completion of the hydro power plant at Ranney Falls, Ont., 10,000 horsepower will be added to the electric supply of Central Ontario system. The plant will be completed about middle of August. In the meantime there has been a power shortage in this district, and the water level of Rice Lake may be lowered temporarily to relieve the situation. It is not unlikely that another power plant may be installed a half mile below Ranney Falls, which would produce 4,500 horse power.

It is reported from Montreal, that the United Brotherhood of Maintenance of Way Employees and Railway Shop Laborers, had reached an agreement with Canadian railways. Negotiations will be continued in regard to reduction in rates of pay made effective July 16. As a consequence of this understanding the employees' representatives have withdrawn their application made to the Minister of Labor for the establishment of a board of conciliation and investigation. The announcement continues that the interim agreement under which wages have been reduced since July 16, fully protects the interests of the employees until such time as definite agreement can be entered into.

Claiming That 77 Cents an hour is barely adequate under present living conditions, James Size, chairman of the Shop Crafts Federation, M.C.R., told the Conciliation Board at St Thomas, that a railway mechanic engaged at ordinary manual labor requires at least $1,958.24 to provide for himself, wife and children. Many of the estimates submitted in coming to this conclusion were exceptionally low, it was claimed, especially the $240 appropriated for house rent and $675.03 for food. Clothing for the mechanic was estimated at $152.11; for the wife, $117.59; for a boy of 12 years, $89.18; a girl of eight years, $81.16, and boy of five years, $50.02 a year. Among other items included in the budget were: Fuel and light, $188.30 per year; maintenance of home furnishings, $79.37; Labor organizations and church, $20; amusements, $30; car fare, $40; insurance, $40, and laundry and assistance for wife, $25.

There will be a Stratford show at Toronto Exhibition this year. The Chamber of Commerce Commission have charge of arrangements.

The Canadian Edison Appliance Co. Stratford, has changed its name to that of Hotpoint Works Division of the Canadian General Electric Company. R. S. Morgan is manager.

Stratford reports unusual activity in building. Sixty-six dwellings have been authorized this year and the total value of all new buildings up to the end of July was $602,181 as against $189,799 last year.

To construct a railway in Peru, 2400 miles long and at a cost of $120,000,000, is the concession for which Robert W. Dunsmuir, Vancouver, B. C., has been recommended to Congress by the Peruvian Government. It is described as one of the largest and most important concessions ever negotiated in Latin America.

The hourly wages of skilled mechanics employed by the American railroads are 25% higher than those paid skilled mechanical employees of other industries in the country at the first of the year. Wage rates in private industry have declined in the past six months, so that the comparative position of railroad shopmen and other shop workers in private industry is at present more marked than generally supposed. These figures are based on a report covering the wages of 388,560 men employed in 1,338 plants, or 73% of all the wage earners in foundries and machine shops as shown by the census of manufactures in 1919, and can therefore be regarded as thoroughly representative of the conditions existing in foundries and machine shops.

Ottawa.—With a population of 5,371,315 Canada exported produce to the value of $33 per head in 1901, as compared with a population of 8,750,000 in 1920 and exports per capita of $147, according to government statistics. The value of exports in 1901 was $117,776,044, as against $1,286,658,709 in 1920.

Ottawa.—Canada's production of gold since 1862 up to the middle of 1922 has reached a grand total of approximately $448,617,107. The silver output of the Dominion during the same period amounted to $265,292,685, while the value of copper produced up to the present time has reached approximately $270,529,237. The amount of nickel amounts to $173,473,403, while $54,000,000 in lead and $20,000,000 in zinc have been produced. The aggregate value of these metals have reached $1,271,912,432.

Ottawa.—A revised estimate of the areas sown to the principal grain crops, hay and potatoes, has been issued by the Dominion Bureau of Statistics. Wheat is reported as occupying 22,628,900 acres, a decrease of 3%; oats 17,183,500 acres, increase 1%; barley 2,732,000 acres, decrease 2%; peas 190,300 acres, or 1% less; mixed grains 865,650 acres, or 1% more. Rye continues to expand, the estimated area this year being 2,480,000, or 35% more than in 1921. The areas sown to hay and clover and potatoes are 10,858,100 acres and 693,600 acres respectively.

Sherbrooke.—The manufacture of finished asbestos products is no longer to be confined to the United States and Europe, but the region supplying practically 87% of the world's supply of the raw material is to engage in the finished manufacture. Plans have been completed by the Johns-Manville Co., Ltd., for the enlargement of their plant at Asbestos, Quebec, where it is expected to be able to take care of all the Canadian requirements of manufactured asbestos products. The Johns-Manville Company is already operating plants in Illinois and New Jersey.

Winnipeg.—Forty-one thousand harvesters will be required to handle the prairie crops this year, it was announced following a meeting of representatives of the railways, western labor commissioners, and the grain trade interests. The rates of wages discussed were $3.50 a day for harvesters and $4.00 a day for threshers. The harvester excursions will continue from Eastern Canada until August 25.

Construction on the various sections of the new Welland canal is now in full swing. The Lyall Co. have 550 men busy on sections 3 and 4. It is planned to lay 2,000 cubic yards of concrete daily at lock 6. Canadian Dredging Co. has four dredges and 250 men at work on section 5, and Porter Bros. have 1,000 men working.

The International Nickel Co., have just completed a large mill for rolling. This is of very large capacity and was installed in order to allow them to speed up delivery on rolled stock of all kinds.

The International Nickel Co. have entered upon an aggressive sales policy which they hope will increase and stimulate the sale and uses of Monel metal. Speaking to Canadian Machinery on this matter, Mr. Peckover, of Peckover's Ltd., Toronto, says: "We have been appointed exclusive distributors in Ontario, and are now carrying complete stocks of all sizes and shapes, so that firms can order direct from our warehouse and avoid delay. Other distributing points are being opened up in other large cities, but as mentioned previously we are the only ones to act in this capacity in Ontario."

Mr. Hollinrake of the A. R. Williams Machinery Co., Toronto, tells us that the plans for the new machinery hall for the Toronto exhibition have now been passed upon. In order to allow exhibitors, and prospective exhibitors, to study these plans, they will be displayed at the present hall this year, and it is more than likely that a special meeting will be held during the exhibition, when all parties concerned will have a chance to discuss the different angles of the situation.

Steel Company of Canada, Hamilton, are making extensive replacement repairs on one of their blast furnaces.

Galt, Ont.—A small fire at the plant of the Galt Malleable Iron Co., on civic holiday caused damage to the extent of several thousand dollars. No reduction in staff will result and rebuilding will be started immediately.

Belleville reports a new industry, the Bassick Mfg., Co., Chicago, manufacturers of the Alemite system of lubrication. The company is repoted to have five branches in the United States and will establish sales branches in Canadian cities.

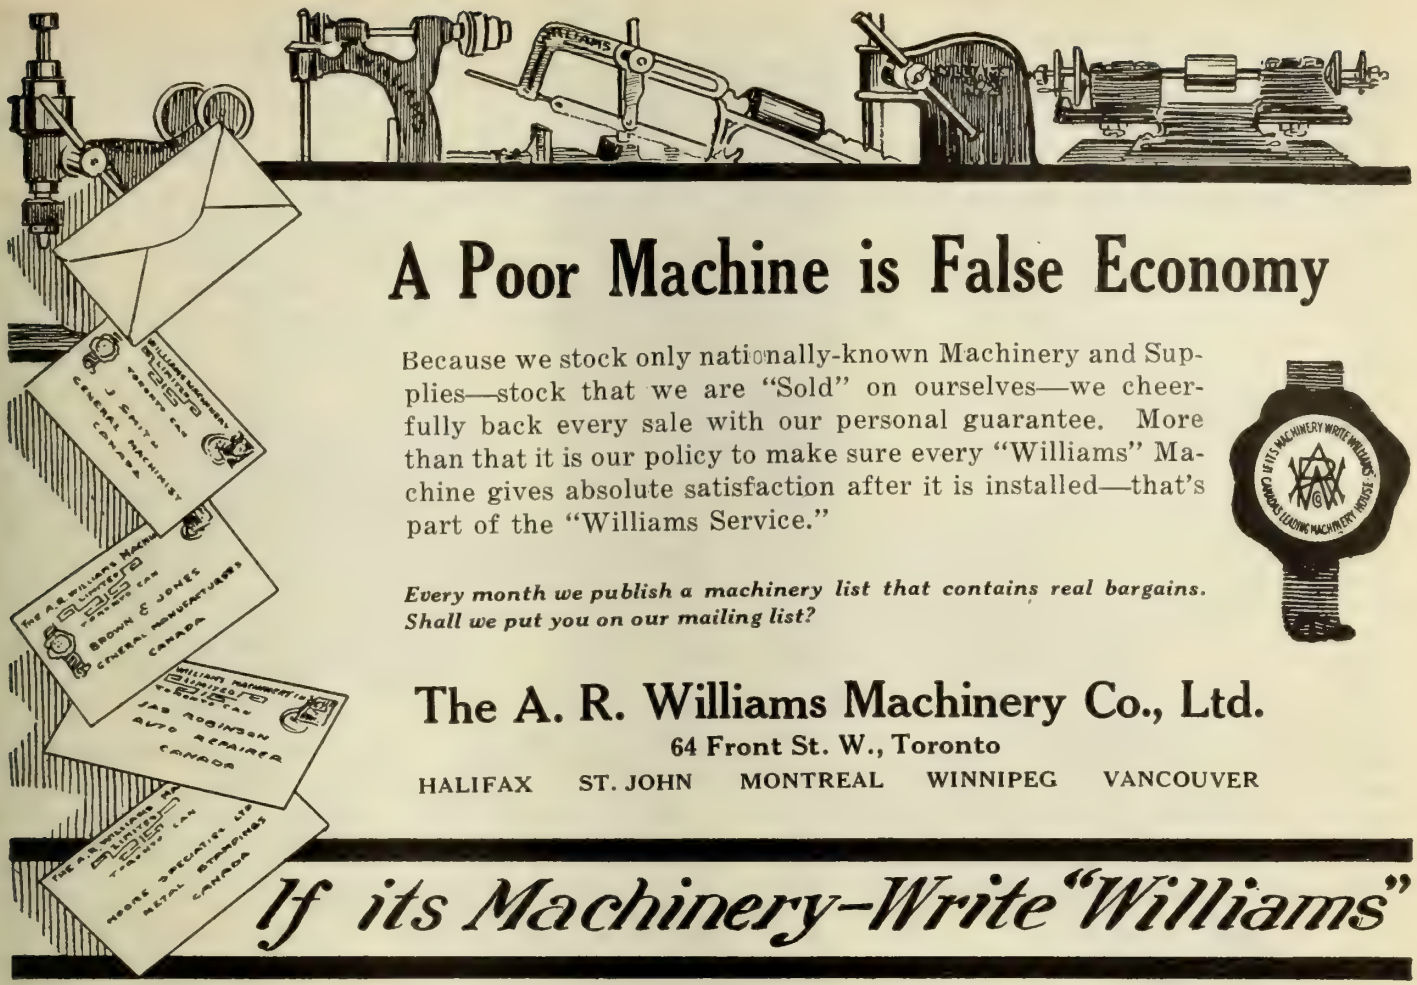
Speaking to A. H. Rolstein, of the Sanitary Wiping Products Co., 239 W. Richmond St., Toronto., Canadian Machinery finds that he has made a reduction of approximately 20 per cent. in his line of sterilized wiping rags, this to take effect immediately.

Sydney, N. S.—Twelve steamers are engaged in the export of iron ore from Wabana, Newfoundland, to Germany via Rotterdam. It is stated at the Sydney headquarters of the British Empire Steel Corporation that about three-quarters of a million tons will have been exported before the end of the calendar year. It is further stated that payment for the ore is being made in English funds.

Speaking to Canadian Machinery, Mr. F. Selway of the Office Specialties Co., Toronto, said that sales show a splendid improvement in their lines. He mentioned that they have just secured several government and municipal orders, these including the suplying of steel upright cabinets, fire walls, efficiency desks, chairs, etc. These orders are coming in from a very wide territory, being all the way from Halifax o Vancouver.

STEEL INDUSTRY FOR B. C.

British Columbia legislature will encourage the establishment of a steel industry in that province. The announcement was made following a Cabinet meeting, to representatives of the Coast Range Steel Company, a $15,000,000 corporation organized a year ago, under H. X. Landahl. According to the announcement, the provincial government will unite with the Imperial and Canadian governments and guarantee as its share, bonds not to exceed $4,000,000. Under plans which have been discussed by the steel people with the British Columbia government and the facilities committee of the Imperial Board of Trade, the total investment in the plant will run to $12,000,000 for the production ultimately of 120,000 tons of finished steel.



A Poor Machine is False Economy
Because we stock only nationally-known Machinery and Supplies—stock that we are "Sold" on ourselves—we cheerfully back every sale with our personal guarantee. More than that it is our policy to make sure every "Williams" Machine gives absolute satisfaction after it is installed—that's part of the "Williams Service."
Every month we publish a machinery list that contains real bargains. Shall we put you on our mailing list?
The A. R. Williams Machinery Co., Ltd.
64 Front St. W., Toronto
HALIFAX ST. JOHN MONTREAL WINNIPEG VANCOUVER
If its Machinery—Write "Williams"

TO BUILD HEAVY MACHINERY

At the annual meeting of Vickers, Limited, held in Montreal recently, A. R. Gillham, managing director, stated that the company has decided to enter into the manufacture of heavy mining and industrial machinery.

They have already completed arrangements with several leading English and American firms to build to their design such patented lines as conical mills, lime and cement kilns, trucks, skips, cages, rotary dryers, coal washing equipment and general mining equipment, and as well, had secured the manufacturing rights for Canada for the Vickers-Petters Semi-Diesel engine. Mr. Gillham stated that the company had secured the rights for Canada, as well as for Vermont, Massachusetts, Maine and New Hampshire, for building sea sleds to the design of A. Hickman of the Sea Sled Co.

He further reported that, in addition to its floating dock and ship repair yard at Maisonneuve, the company this year had opened an office on the harbor front, to deal with ship repairs while in berth. The following were elected as the board of directors of the company for the ensuing year: Sir Trevor Dawson, Sir Vincent Caillard, Sir James McKechnie, Preble Macintosh and A. R. Gillham.

UNEMPLOYMENT INSURANCE

That unemployment is a problem for industrial management rather than public insurance is the conclusion arrived at by the U. S. National Industrial Conference Board. Discussing unemployment insurance in theory and practice, it is claimed that the basis for applying public insurance to the relief or prevention of unemployment without enormous cost, did not exist. Among other things, it is pointed out that the political organization of the country would make the adoption of a national system of unemployment insurance impossible without constitutional changes, and the country's vast extent, diversified industries and social composition would create under such a system an administrative problem of gigantic proportions and cost. If, on the other hand, a system of unemployment insurance were to be built up by the separate states, the complications arising from attempting co-operation between the states in the placement of workers and adjustment of compensation would likewise present administrative problems of difficulty, especially in view of the probability that the legislation in the separate states would differ widely. In addition to these difficulties is the fact that there does not exist in most states either a system of labor exchanges or comprehensive organizations of wage earners, either one of which European experience indicates as a necessary basis for a public insurance scheme.

TOURISTS LEFT MUCH MONEY

Department of Customs reports that during the past year, 617,285 cars toured Canada, as against 93,300 in 1920. All but two thousand cars remained in the Dominion for less than one month. This motor traffic meant an expenditure in Canada of $108,000,000, and it is estimated that on a basis of five per cent. "improved roads are worth over two billion dollars without taking into account the service they render Canadians themselves." The parks branch estimate of expenditure in Canada by motor tourists is based on a stay of seven days for the larger number of cars and thirty days for the smaller number, while the daily expenditure for the former is put at $25 and $20 for the latter.

With the installation of camping sites throughout the country, the touring traffic will undoubtedly increase and the present year is likely to show a record. All of this means good business to the garage, or to machine shops equipped to do repair work, regrinding, etc.

PERIOD OF BETTER BUSINESS

(Continued from page 40)

tivity, writes J. A. McGibbon, Oshawa Board of Trade. "All factories are busy and there has been very little unemployment. The Pedlar people have been filled to capacity with orders along all lines of work. The motor industry has been very active, and the new models are being well received.

"Building operations are progressing favorably both in business and residential lines. In fact there has been more activity than usual in this line. The hospital is building a new wing, called the McLaughlin Memorial Wing, and St. George Anglican Church has commenced the erection of a new church. The Alger Press is preparing a new home, due to increased business. Several additions to buildings are in course of construction.

"The W. E. Phillips Co., Limited, who are occupying the former Thornton Rubber Co. factory, are a new concern and are already showings signs of growth.

"The Feldspar Glass Co. are making additions in the shape of large shipping rooms, while the Potteries Company, Ltd., are reported to have purchased the Reed property on the Kingston road, a two story brick structure.

"The McCulloch Brass Co., have taken over the works of the Parks Foundry Co., and are reported to be very busy at the present time."

PITTSBURG

(Continued from page 39)

for two months at 75 per cent., which is approximately the present rate.

Connellsville steam coal declined until it reached $6.00 August 1, whereupon some buyers entered the market again and prices have stiffened to a range of $7.00 to $7.50, fully $1 below the recent high point on this movement. Connellsville foundry coke is $15 to $15.50, both demand and offerings being limited.

The pig iron market has disappeared except as to small prompt lots. Furnaces are in no position to figure closely on prices for fourth quarter and consumers are indisposed to negotiate, realizing that this is no time to buy, when nearly all merchant furnaces are out of blast and a new market will have to be made when coke becomes available again to the ordinary buyer. There is only a prompt, practically a spot, market in pig iron, and this is higher, at $26 for Bessemer and $27 for foundry, valley. Last sales of basic were at $25, valley, representing the market's recovering the $1 loss sustained early in July.

The oxygraph is a machine for operating an oxy-acetylene cutting torch, and is designed to reproduce any outline drawing, pattern or template in full or half scale, cutting to the shapes in wrought iron or steel.

Introducing

E. T. SPIDY
Asst. Supt. Dominion Engineering Works.

BORN in 1887 in Brighton, England, receiving his early schooling in Australia and New Zealand and returning to England to finish his education, completing same by taking Mechanical Engineering Course at Brighton College of Technology, is a brief history of the early years of the assistant-superintendent of the Dominion Engineering Works, Limited, Rockfield P.Q. Immediately after this, Mr. Spidy became an apprentice in the shops of the London, Brighton and South Coast Railway. Five years were spent completing the apprenticeship, after which he worked for a year and a half in the same shops as a tool fitter. In 1909 he came to Canada, and entered the employ of the Canadian Pacific Railway in the piecework department of the Angus shops. At that time the Angus shops were being reorganized by H. H. Vaughen who had employed as management engineer, H. L. Gantt to introduce schedule and efficiency methods. Mr. Spidy's duties kept him in close touch with Mr. Gantt and he frankly admits that it is his contact with him and other big men, with big ideas, that have made his progress.

In 1911, he was transferred to the C.P.R. Toronto shops and in 1912 to the C.P.R. Winnipeg shops as asst.-general foreman with instructions to install the schedule methods established at Angus. Later, he was made shops engineer at Winnipeg when the whole plant maintenance was included in his duties.

During his last year at Winnipeg, Mr. Spidy lectured in the University of Manitoba on power plant design and machine design. At this time he felt a desire to broaden his experience and to apply his efficiency and production ideas to industrial plants.

Thus, in 1917 he accepted the position of production engineer at Canadian Ingersoll Rand Company's Sherbrooke plant. Late in 1919 however, the call from his previous associates on the railway proved too strong and he returned to the C.P.R. Angus shops as production engineer, where he remained until 1921 when he accepted the appointmnt of assistant-superintendent of the Dominion Engineering Works, which position he still holds. He is an associate member of the Engineering Institute of Canada and of the American Society of Mechanical Engineers.

Mr. Spidy insists that the study of production is the most fascinating in the world. Outside of engineering his leisure time is devoted to his family, who, including himself are musicians and the younger members he hopes are coming musicians. He also is an ardent fisherman and hopes some day, he says, to be a real fisherman.

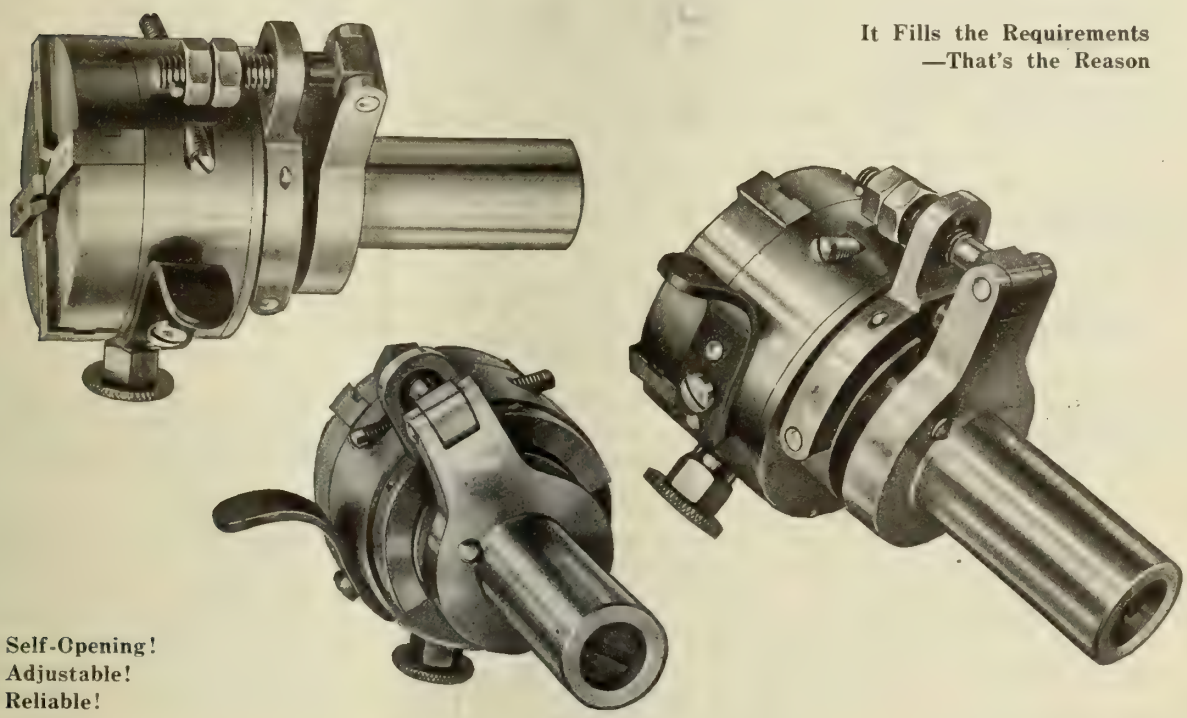
ELECTRICAL TRADE BEST

At the annual meeting of Vickers', Ltd., Sheffield, Eng., the chairman, Douglas Vickers, reviewing the year's operations, stated that the electrical trade still showed up best. There were few enquiries for ships, steel products or railway materials, but motorcars on the other hand were selling quite well. As to the cause of bad trade, the condition of Russia and impoverished Central Europe seemed inadequate as an explanation, and the chief cause must be at home, as far as engineering was concerned. Customers for engineering products, machinery, etc., were on strike. These goods were purchased almost entirely on capital account and paid for out of profits or raised by new subscription. Excessive taxation had almost stopped the former and as to the latter, investment of new money in plant at prices that were still high as compared with past years, offered little attraction to the investor, who could get a return from trust securities that compared not unfavorably with that of ordinary shares before the war. For the moment the outlook was still gloomy but there were points that indicated that the skies might clear.

A pantagraph frame supports a machine cutting torch and the small electric motor that operates the feed gear; this comprises a knurled driving wheel or disc geared to the motor through worm and spur gearing and mounted in the fork of a swiveled vertical member. This part is free to turn in any direction required. Thus means are provided for moving the torch mechanically in any horizontal direction at a uniform rate, the speed of which may be varied within wide limits.

The High Mark In Screw Cutting

The Geometric Style DS Die Head touched High Mark in popularity at a time when Buying was at Low Mark



It Fills the Requirements —That's the Reason

Self-Opening!
Adjustable!
Reliable!

Brown & Sharpe Automatics, as well as other single spindle machines, needed just such a Screw-Cutting Die Head—and the Geometric DS is it. With a DS Die Head on the machine there is:

No reversing of the spindle to back the Die Head off the threaded work.

No stripping and shaving of threads, for the Die Head floats to suit the thread being cut, and does not depend on the turret feed.

No burden of tripping the Die Head, because of the easily adjustable lever trip, which lightens the reaction on the threads as they are cut.

No shock and wear, even when closing the Die Head rapidly, because of the spring closing attachment.

No face plate necessary, allowing the use of projecting chasers when cutting is close to shoulder.

No cutting of taper threads for the chasers have long bearings in the Die Head skeleton and are supported by hardened keys, which prevent tilting.

Consider the economy of these Die Heads with micrometer adjustment, over the use of a button die with no adjustment.

Geometric Die Heads are sent on trial to reliable concerns.

When answering advertisements kindly mention Canadian Machinery

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

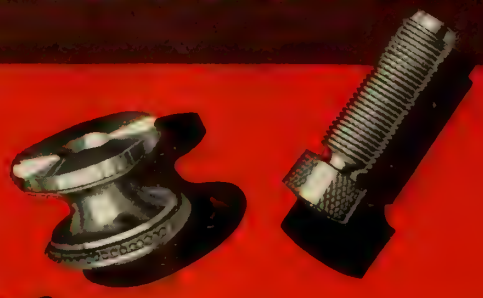
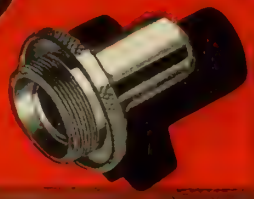
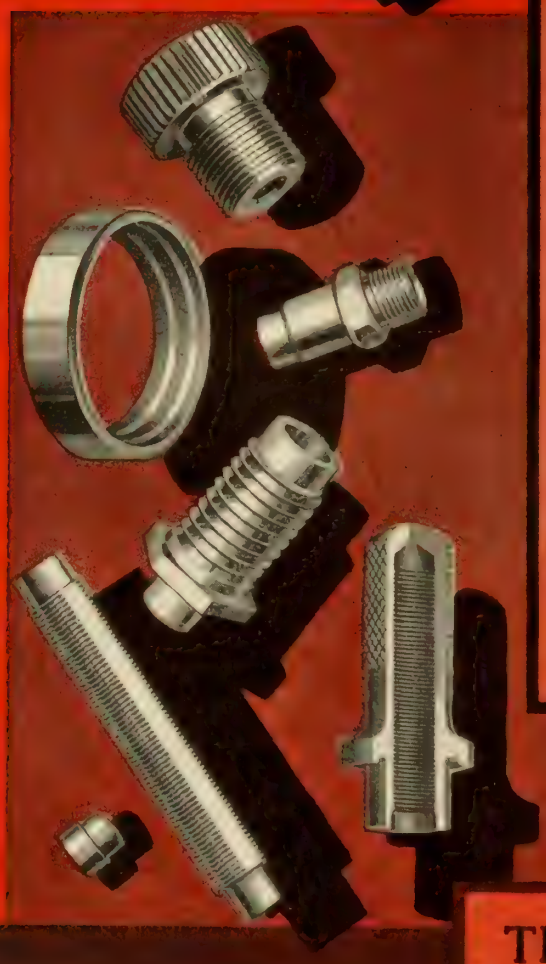
Namco Parts
For Auto Accessories







It makes no difference whether you need—One thousand tiny Adjusting Screws—Ten thousand Hardened and Ground Spring Bolts—or any other kind of milled parts up to 2¼ in. diam. Our well-equipped product plant is at your service.

Extensive knowledge of special operations and a mechanical equipment for practically every variety, enables us to take care of new and highly specialized products without the loss of time caused by slower methods, or the cost of experimenting to find quicker ones.

Standard Cap and Set Screws, also Finished Nuts and Studs from stock.

Genuine Oak Tanned Leather Belting

OF ALL the factors that enter into the making of D. K. McLaren's Belting, there is one of first importance—the tanning. Money will buy machinery, buy tools, men and raw materials, all, perhaps, of the best. But only experience can buy the right process. Only years of doing, of testing, investigating and proving, can determine how leather should be treated.

Service on the pulley, hard work under adverse conditions, have demonstrated the value of the D. K. McLaren's process of Genuine Oak Tanning.

Genuine Oak Tanning—the long-time process—is the secret of our success, and on any drive and every drive you designate will prove the secret of service to you.

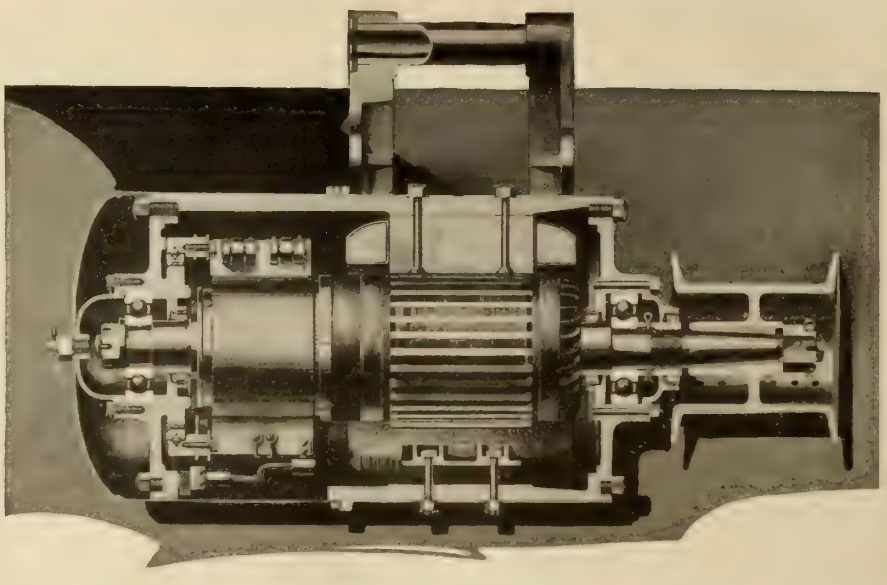
SKF



Uninterrupted Car Lighting Generator Service Depends Largely on Bearing Performance

One of the biggest single factors in the successful lighting of railway cars is the use of ball bearings in car lighting generators. Shocks and jolts caused by passing switches and crossovers and the continual jar of heavy truck suspension tend to play havoc in all but the best of bearings.

SKF marked deep groove ball bearings have demonstrated their ability to stand these severe operating conditions and to thereby maintain generator service. The construction of the deep groove ball bearing furnishes exceptionally high carrying capacity for both radial and thrust loads. Friction is practically eliminated, lubrication is needed only once in six months, and after years of operation wear is negligible so that the armature position is permanently maintained and the danger of burnouts caused by armatures falling on the pole pieces is removed.

In fact standard equipment in car lighting generator bearings to-day is recognized as meaning equipped with **SKF** marked bearings.

No. 5 Cylinder Grinding Machine in the plant of H. E. Bourassa, Montreal

A Big Wide Open Opportunity

CYLINDER REGRINDING

Think of all the cars in your territory that have gone sluggish and pepless because of worn, leaky, out-of-round cylinders. When there's loss of motor power, it's to your advantage to suggest regrinding.

This is your opportunity. If equipped with a Landis cylinder grinding machine you can see that the work is done quickly and economically and besides you can branch out with a side line that would make a profitable business in itself alone.

Many men are doing it all over the country and have built up a profitable business and furnished real service to the motoring public.

Now is your opportunity. Ask for further details.

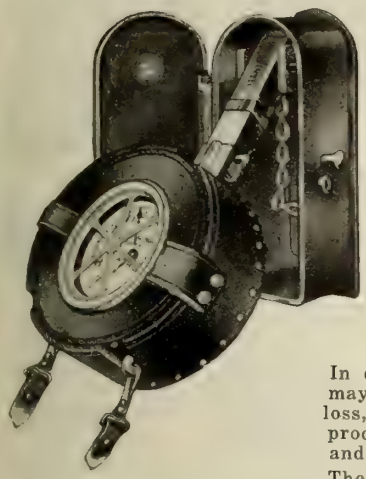
Why Take Chances ?



The HARDINGE SYSTEM Protects You

In case of fire, full insurance may pay you for your property loss, but what about loss of production — the laid-off men and general disorganization?

The thing to do is to **prevent** loss and that is just what the Hardinge Watchman's Clock does. It keeps your watchman "on the job" whatever his inclination. With the Hardinge System installed you can rest easy knowing you are taking no chances. It's an **assurance against** fire or robbery and **insurance for** your steady income and production.

You're A Mechanic—So You Know

That a Knurling Tool can't be expected to produce uniform work, or even last any length of time, unless it is self-centering (with as little lost motion as possible,) and the Knuckle or Joint has ample bearing to resist the severe strains of both end and side thrust.

As the product of practical men — specialists in fact — the **Armstrong Knurling Tool** naturally embodies these essentials of construction. These, together with excellence of design and high quality material and workmanship, are factors of its wide popularity.

The Bowser Oil Bank Will Give You a Check

"Bill, that chewing gum man has the right idea for oil. You know, he says: 'Sealed tight keeps right!'
"Do you realize, that, since we put in that Bowser equipment to handle oils, our lubrication trouble just disappeared?"
Bowser tanks assure the constant operation of your machines without those expensive shut-downs caused by out-of-service equipment—because the all-metal oil-tight construction of Bowser tanks prevents dirt and grit getting into the oil, robbing it of its lubricating qualities.
Lubrication trouble, thief of time and upsetter of production schedules, can be completely eliminated by Bowser equipment in your plant, just as it has been in hundreds of other plants—names on request, of course! And not only is the oil maintained at its full lubricating efficiency, but all waste and spillage are eliminated—thereby the fire hazard is wiped out.
Booklet C-13 is of vital interest to you. It will be sent upon request. Or, better still, permit one of our engineers to make a survey of your plant—you will find his suggestions worth while if you wish to save money and to increase production.

Bowser Equipment is MADE IN CANADA by

S. F. BOWSER & CO., LTD.
Toronto - - Canada

Branch Offices and Service Departments throughout Canada and in principal cities abroad

BOWSER ESTABLISHED 1885
ACCURATE MEASURING PUMPS

Bowser Products

For Handling Gasoline and Oils Wherever Sold or Used

Filling Station Pumps and Tanks for Gasoline.
Portable Tanks for Oil and Gasoline.
Storage and Measuring Outfits for Paint Oils, Kerosene and Lubricating Oils.
Carload Oil Storage Tanks.
Power Pumps.
Dry Cleaners' Underground Naphtha Clarifying Systems.
Richardson-Phenix Oil Circulating and Filtering Systems and Force Feed Lubricators.

Snagging the Rough Casting With NORTON Grinding Wheels

THE modern way to remove gates and fins from castings, all sizes and kinds, is to use a grinding wheel of correct abrasive, grit, and grade to remove the surplus metal in the least possible time. A slow cutting wheel raises the overhead cost tremendously.

Use Norton **Alundum** Wheels for snagging all steel and annealed malleable iron castings.

Use Norton **Crystolon** for snagging all gray iron, brass, and aluminum castings.

We will select the proper wheel for you, if we know just what the composition of your metal is, the average size of your castings, and the type of machine you use.

Off-hand grinding on a floor stand.

Grinding with a swing-frame machine.

Try one wheel and draw your own conclusions

Flexible shaft equipped with Norton Wheel.

Emergency Methods that Proved Effective

How Difficult Problems Have Been Solved, Very Often On Short Notice—Repairing a Wooden Tooth Bevel Mortise Gear—Impromptu Internal Grinding—Wooden Centering Devices—Extending a Planer Bend—Shop Ingenuity

IN spite of the best laid plans every shop runs up against an emergency proposition periodically. In the case of a manufacturing plant the nature of these emergencies often is such that it becomes an executive's problem. In the smaller shops, where jobbing and contract work are the only activities, a fairly large proportion of the regular run of work may be classified under the term "emergency," and often these problems have to be solved in the shop and not in the office. The executives of these small shops do not always place at the disposal of their foremen and mechanics the latest and most up-to-date equipment for special jobs. For this reason, the small shopmen need to be able to plan a piece of work on a moment's notice, and then be able to execute it with whatever equipment there is at hand.

It is often the case that such work is placed with the shop by an establishment that has been unfortunate enough to have had a breakdown, and all, or a part, of its operations are suspended until repairs are effected. Furthermore, it is frequently the work is undertaken because the firm in question have been good customers in the past, or that they will have considerable work in the future. Thus one particular job may not be attractive, but is accepted in order to give service to a good customer. The amount that should be charged up to the job to enable that shop to come out even, in many cases would seem excessive, so it is up to the mechanic to complete the work, often under a disadvantage, as economically as possible. Work, in most of these cases, must be started at once, as every hour is valuable. The shopman has no choice but to visualize the job as a whole and plan it on short notice.

Cogging a Mortised Tooth Gear

One of the most common ways of harnessing vertical shaft turbine water wheels, up to about twenty years ago, was by means of wooden teeth bevel mortise gears, mating with cast iron pinions. In a number of isolated plants to-day this form of gearing is still used on the water wheel drives. In this gearing the wooden teeth wear out more quickly than the iron pinion teeth, which necessitates these wooden teeth being replaced at intervals.

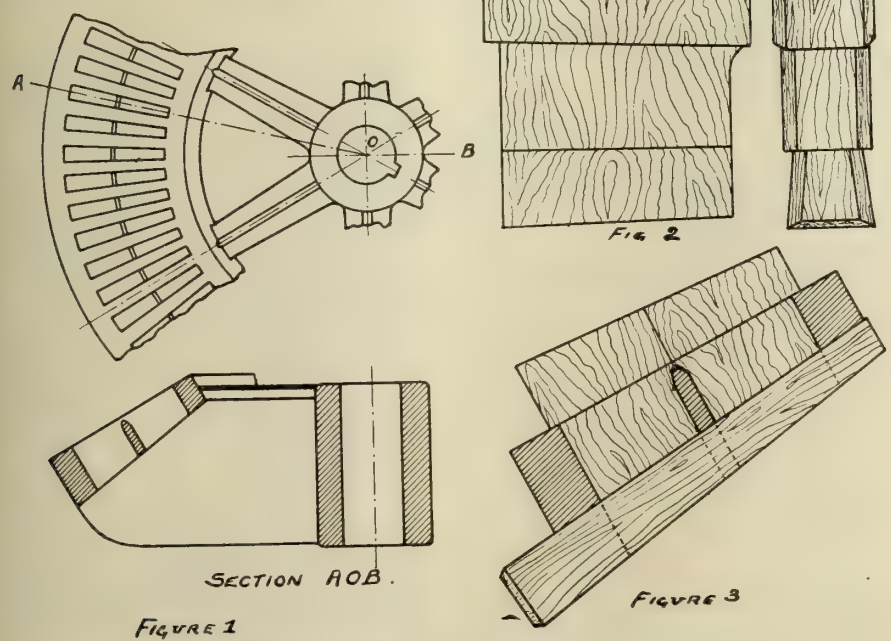

Fig. 1.—Section of bevel mortise gear casting. Fig. 2.—Wooden cog for bevel mortise gear. Fig. 3.—Rim section of bevel mortise gear with cog and gear in place.

In a paperboard mill in Ontario one of these gears was run until the teeth stripped. A local machine shop was immediately called on the phone and the order for the repair of the gear was thus given. The gear was placed on the way freight the same day, and next morning was delivered to the shop.

This particular gear had sixty teeth, four inch circular pitch, with a face of fifteen inches. The slots into which the wooden teeth mortise were cored in when the wheel was cast, and were not machined. Thus they were slightly irregular, and could not therefore be depended upon for the spacing of the teeth. A section of the gear is shown in Fig. 1. The teeth were sawn out of hard maple stock in two sections, the large end finishing up seven inches face and the small end eight inches face. One of the large end cogs is shown in Fig. 2. The small ends were fitted and driven into the casting last. Then the large ends were fitted and riven. The small openings between the solid heads of the cogs were plugged with pine wedges, to prevent the splintering of the heads when turning. Then the gear was placed on a mandrel and then in a lathe where the turning was accomplished. The gear was next mounted on a dividing head which was placed on a planer table. The gear was allowed to overhang the table as shown in Fig. 4. A planed surface was placed in front of the gear just below the centre line of the dividing head arbor. A surface gauge was carefully adjusted so that the point was coinciding with the level of the centre line of the arbor. This surface gauge was used to scratch a line in the centre of each tooth. The ends and face were marked. Then each section of each

tooth, and the slots in the gear, were numbered, and the teeth were driven out for dressing. Templates of sheet zinc had been filled and the profile of the teeth was scratched on each end of each section of the wooden cogs. A formed fly cutter had been made to conform to the profile of the zinc templates. This cutter was attached to a vertical shaft. A special vise was rigged up and placed on a planer table. The teeth with solid heads were clamped in the vise, which was set at such an angle that when they passed the revolving fly cutter, one side of the tooth profile was formed. Fig. 5 diagrammatically shows the general arrangement. The vise was arranged so that a slight vertical adjustment was possible, so that each tooth would be formed symmetrically about the surface gauge centre line. Small wooden stops were placed in the vise which permitted the quick clamping of successive wooden teeth or cogs, with only the vertical adjustment to be made. The shaft driving the cutter was belted to the planer counter shaft through the medium of a special counter shaft mounted on the floor, and a quarter turn belt. The speed of the cutter was approximately 1,200 r. p. m. The planer was used to feed the work past the tool, the regular cutting speed of the planer not being changed. It may be here stated that the machine was not a high speed tool, and the table travelled at about thirty feet a minute. Two cuts, one on each side of the cog, were necessary on each section of the two-piece teeth. When the cutting of the profile on the teeth was accomplished, the teeth were redriven into the wheel. Then the keys of Norway pine were fitted and driven. Fig. 3 shows a section of the gear with a key in place. The profiles of the teeth were then smoothed up with sandpaper, and finally were given a coat of linseed oil. Fig. 6 shows details of the vertical shaft, fly cutter, block and special collars. Fig. 7 shows the gear skidded and ready to be shipped out.

It may be here questioned why the gear teeth were not cut when the gear was on the dividing head. It was found to be very difficult to rig up a cutter to get at the teeth when they were in the wheel. This could have been done very nicely had there been time to have obtained one or two castings and to have machined them. Then again there was very little provision in the apparatus used to prevent the gear slipping on the mandrel of the dividing head while the cutting was actually taking place, and if this occurred, the teeth would be improperly spaced. The simple scratching of the line on the teeth exerted no pressure, or tendency to turn, to speak of, and thus it appeared reasonable to assume that the indexing thus obtained was proportionately as accurate as the spacing of the worm wheel in the head.

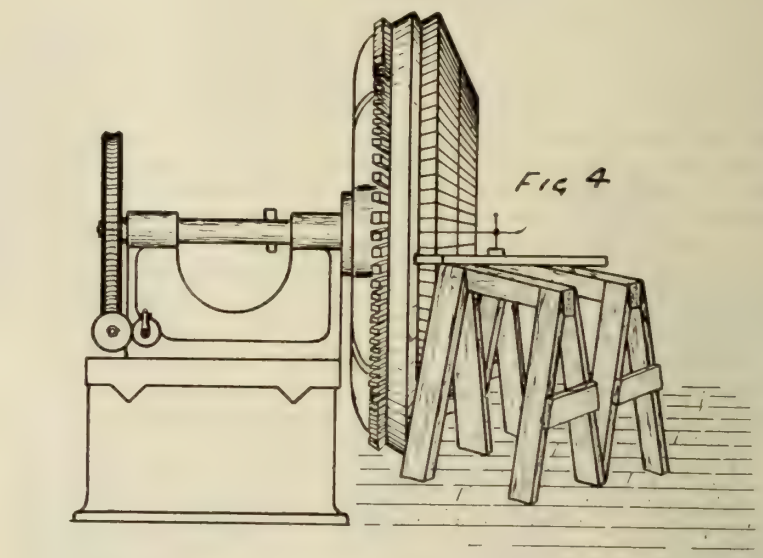
The gear was rushed back to the paperboard mill and was immediately placed in commission. Reports some months afterward stated that it had given perfect satisfaction.

Impromptu Internal Grinding

During the period when shell manufacturing was at its height and all kinds of material and supplies were in heavy demand, many emergency methods were employed. In one shop, chilled cast iron dies for nosing the 4.5in. shell were used. On one occasion when it became necessary to change dies there was only one extra die in stock. Upon placing this die in the hydraulic nosing press it was found to be a little rough, causing it to be somewhat difficult to quickly release a shell after nosing. The die was taken out and chucked in a lathe. An aloxite grinding wheel was placed on an arbor, which was clamped in the boring bar holder of the lathe. The grinding wheel was secured so that it could not turn on the arbor. The lathe was revolved at top speed with the open belt. By manipulating the compound rest, the die profile was ground and polished in a short time, and when again placed in service functioned properly.

In the case of a small lot of fifty bevel gear castings which were being bored, a very useful wooden device was designed. The work was executed on an engine lathe. The face plate was placed on the machine, and two pieces of hard wood were bolted to it. The wood was 2½ inches thick, and covered a space somewhat larger than the diameter of the gears to be bored. The wooden pieces were bored out to fit the bevel of the teeth in the gear castings. The castings were simply placed in the wooden fixture and a clamp was used to hold them securely, the centering being accomplished by the pieces of wood. The result was that the time consumed in placing castings in the lathe was reduced to a minimum.

Wood can often be used to good advantage in making special steady rests for work that cannot be taken care of by the regular form of equipment. Templates for small lots of drilling can be made of wood. Of course, wooden jigs and fixtures will not have permanent accuracy, but they do good work when it is only required to machine small lots of work quickly in a repair shop.



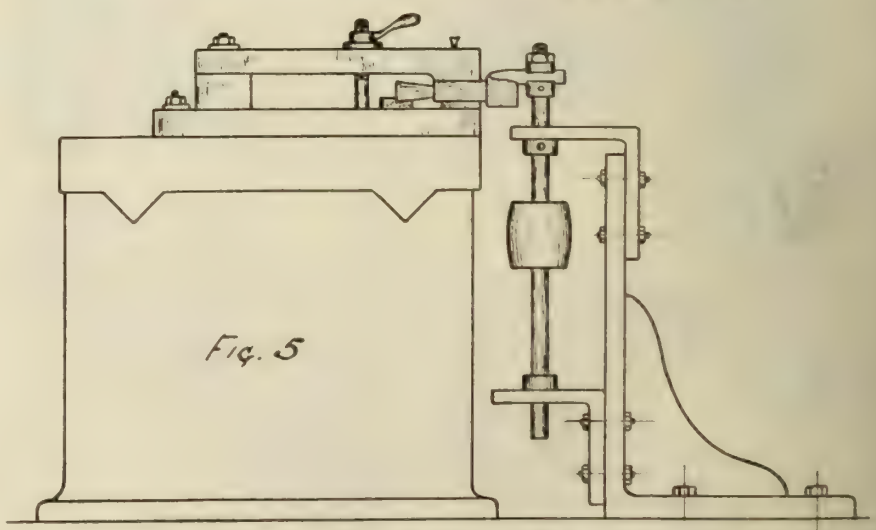


Fig. 4.—Indexing teeth in a bevel mortise gear previous to cutting same. Fig. 5.—Cutting profile in wooden teeth.

A short time ago there came to a small shop a cast iron solid pulley eighty inches in diameter, in which it was necessary to cut a second keyway on the quarter with one already cut. The job caused the foreman some thought before he finally solved the problem. He removed the table from his largest shaper, which was only a small machine, and proceeded to bolt the pulley to the shaper frame. Cast iron blocks were placed between the pulley hub and the shaper column. These blocks were planed thinner at one end than at the other. This secured the pulley slightly out of the vertical, so that when a bar and keyseating tool were used in the ram, the keyway was cut slightly deeper at one end than the other. It was only necessary to block the pulley at the proper height, and the cutting of the keyway became a simple matter.

Extending a Planer Head

A machine shop is often up against the problem of planing a piece that is too wide to go between the uprights. This type of job is sometimes handled by placing a tool in a bar and thus extending it in front of the head some little distance. This necessitates slow work as the bar tends to spring upward when the tool enters the work, if the cut is at all heavy. When this occurs the cutting edge of the tool is dragged over the work on the return stroke and its edge ruined. This condition of affairs is further aggravated if the planer takes its feed on the return stroke.

A rather good device, which was noted not long ago in a Montreal shop, was one that carried the entire head, hinged block, tool holder and all, out from the cross rail about thirty inches. The device was seen on a 36 x 36 inch planer. The extension block was a hollow cylinder flanged at both ends. It was drilled to fit the bolts that slide in the circular ways in the head, and the regular planer bolts were used. All of the power horizontal feeds were still available. The vertical feed could only be operated by hand, however. The device only increased the capacity of the planer to a nominal extent, but this shop found it very useful on a large number of jobs. The cylindrical shape of the cast iron extension block was such that it resisted distortion. Of course, with a thirty-inch extension there was some deflection or spring, as each piece of the machine was susceptible to this influence and the net cumulative effect was present. At the same time it was far more rigid than such devices as a tool on a bar.

Shop Ingenuity

From day to day many such jobs are done, and unfortunately most of them do not receive more than passing attention, as they are usually considered all a part of a day's work. The ingenuity displayed in our machine shops to-day is greater than ever before, as a wider range of work is presented to them. Machine shop equipment is also covering a wider field. But after all is said and done, it is often the small shop that displays the greatest originality in extracting itself from emergency situations, as it must do so with comparatively meagre equipment.

There are two classes of employees—those who ought to be "let out" in time of depression, and those who take on additional work.

CANADA'S MOTOR EXPORTS GROWING

IT is predicted that within a decade Canada will be the greatest automobile exporting country in the world, says The Industrial Digest, New York. Several of the world's largest producers of motor vehicles, according to recent reports, are now handling all their export business from the Dominion, while the largest individual manufacturer of motor cars has for some years filled all orders from the British Dominions and possessions from his plant on the Canadian side of the St. Clair river.

The progress of the automobile export business in Canada has been comparable to the remarkable development which has taken place in the home market. With a population of about 9,000,000, Canada owns and operates over 400,000 automobiles and trucks. A decade has witnessed an increase in automobile ownership of twenty fold. While such a phenomenal advance is not to be expected again, continuous replacement of motor vehicles is assured. Within the next ten years, Canada will offer a home market for more than 500,000 motor vehicles for replacement purposes only. In that time, it is believed the market will expand its demand from 50,000 to 60,000 motor vehicles per annum, which it now offers, to beyond 100,000 motor vehicles.

In the automobile manufacturing concerns alone, employment is given to about 8,000 wage earners and 1,200 or 1,500 salaried hands. Wages paid total about $10,000,000 and salaries about $3,000,000. Manufacturers of automobile supplies pay salaries amounting to nearly $1,000,000 every year and wages of more than $5,000,000.

In many cases, however, automobiles are assembled rather than manufactured by the Canadian companies sponsoring them, so as the volume of automobiles imported falls off, in proportion to sales of cars made in Canada, the volume of automobile parts imported manifests a decided increase.

The most recent information compiled about the Canadian automobile industry is that contained in a preliminary report on the automobile industry in Canada for 1920, which has just been published by the Dominion Bureau of Statistics. It shows that $67,157,045 worth of material was consumed by that industry during the year 1920. The largest individual item was $12,972,801 for automobile bodies, the next largest, $8,810,486 for automobile engines. In raw materials the principal item of consumption was steel, figured at $1,006,848. Iron and steel castings consumed are stated at $1,763,812 and $1,875,358 respectively.

A Swedish engineer is said to have worked out a method which makes it possible to obtain a very cheap fuel from the residue or lye which results from the manufacture of cellulose.

Does Acid Pickling Cause Brittleness in Steel?

Light Scratches Will Impair Cold Working Properties—May Be Removed By Taking Off a Thin Layer of Material—Heat Treatment Also Beneficial—Excessive Pickling Decreases Toughness

THIS question appeared some time ago in the monthly transactions of the American Society of Steel Treating. In the reply it was stated that one writer claims that the embrittling action of pickling is due to an eating out of the grain boundaries in steel. In a previously printed treatise on the subject the contention of the author was that aid by three micrographs which represented the following conditions:

1. Normal steel before pickling; 2. Steel made brittle by pickling and 3. Steel made brittle by pickling and restored by heat treatment. In these micrographs the grain boundary lines were shown to be widest in the brittle material and of less but about equal width in the other two samples. Measurements were given stating that the grain boundaries are about three times as wide in the brittle steel as in the others.

Pickle brittleness cannot be attributed to widening of the grain boundaries on the basis of the evidence given in this article. This does not mean necessarily that a selective attack on the grain boundary material by the pickling acid is not a factor in causing the brittleness. It would be important to establish whether the fracture follows the grain boundaries in steel which has been made brittle by pickling. If it does not, then the brittleness cannot be attributed to this cause. If it does follow the grain boundaries, brittleness can be attributed to some grain boundary condition which may or may not be a widening caused by corrosion. In looking for information on this point it was pointed out that most of those who have had experience with this difficulty have not observed the path of rupture. One metallurgist says, however, "furthermore the brittleness caused seems to be an intercrystalline one, that is, the fracture seems to follow the grain boundary."

Another writer has suggested that the brittleness may be due to a notch effect consisting in the formation by the pickle acid of minute grooves or notches on the surface of the steel especially at the grain boundaries. This would cause the metal to begin to tear at the grain boundaries. The suggestion is quite logical inasmuch as it is well known that even very light scratches on the surface of steel sheet seriously impair its cold working properties. If the idea of surface notches is correct then the brittleness should be confined chiefly to the surface of the metal and should disappear after the surface layer is removed. There are many indications that pickle brittleness is a surface phenomenon. To begin with it is practically unnoticed except in material of small cross section chiefly sheet and wire. This may be explained in part by the fact that heavier sections such as bar stock and steel forgings are as a rule not subjected to any deforming process, which would reveal brittleness even if it exists. Steel sheet and wire are especially apt to show up this defect, because of the severe deformation they are subjected to in fabrication.

Still another authority states that pickle brittleness can be removed by taking off a very thin layer from steel sheet, perhaps not over about 0.003 inch. This certainly indicates that the surface layers are at least the most affected, which is bound to be the case since the acid begins its attack on the surface. Opinions have also been expressed that brittleness permeates the entire cross section, especially in the case of sheets. The truth of the matter is probably that the action is similar to that of carbonizing, beginning at the surface of the metal and penetrating to a greater depth the longer the pickling is continued.

There is general agreement that this type of brittleness can be removed readily by heating and a common heat treatment seems to be about 10 hours at 400 degrees Fahr. It has also been brought out that no trouble is encountered from pickle brittleness when the metal is heated in the natural course of fabricating operations after the pickling process.

The orthodox theory is that the brittleness is due to the absorption by the steel of the hydrogen liberated in the pickling process. The removal of brittleness by heating is then supposed to be due to the expulsion of hydrogen. If we accept the "notch theory" of brittleness then we must find some other explanation of the removal of brittleness by heating. It has been suggested that this is due to the removal of a small amount of metal by oxidation thereby rounding the corners of the notches or removing them altogether. It appears, however, that pickle brittleness can be removed by heat treatment at a temperature so low that no visible oxidation occurs, and even disappears slowly when the steel is allowed to stand or age at ordinary temperatures. This can be explained on the basis of a slow loss of absorbed hydrogen, but it is difficult to explain on the basis of removal of notches from the surface.

It is still more difficult to account for the restoration of ductility if we consider that the brittleness is due to the actual removal of grain boundary metal. The most that we can concede the grain boundary theory is that the grain boundaries are particularly affected either because of a local penetration of hydrogen or because of the notch effect mentioned.

In connection with this question the writer answering the question stated that he had made some inquiries as to the prevalence of pickle brittleness and found that the largest producers of material in which this defect might be expected do not seem to have much trouble with it. One large company reports that much of its product is not heat treated subsequent to pickling and is subjected to severe deforming operations by customers without any difficulty. It is to be expected that the effect of the brittleness developed will depend considerably on the pickling conditions. Some alternating bend tests by Prof. H. O. Arnold on steel bars showed that doubling and trebling the time of pickling continuously decreased the toughness of the steel. It seems, therefore, that if proper care in pickling is exercised and especially if some time elapses between pickling and use, brittleness is the exception rather than the rule.

BETTER DEMAND FOR ELECTRIC TRUCKS

What appears to be a sign of the times is a statement recently made in the Electrical World to the effect that increased activity is developing in the industrial truck field. This demand for trucks and tractors will be stimulated by a possible tie-up of railroad transportation facilities especially for short haulage. The report states that:—"The resumption of production on a substantial scale by large manufacturing plants in many industries has resulted in the putting into service of internal transportation equipment which in not a few cases has been but partly used since the close of the post-war boom. The pressure upon factory managers to reduce unit costs is leading to more inquiries as to the applicability of trucks and tractors in labor and time-saving tasks. Some of the older units of equipment also have approached the point where replacement is worth considering and the demonstration by manufacturers' engineers that trucks can be economically justified in much smaller plants than used to be the case is helping this business. Some difficulty is being encountered at present in the supply of steel for truck and tractor frames but this is believed to be only temporary.
